Macintosh: Sharing A LaserWriter II With A VAX

=====

This article last reviewed: 20 January 1989

If you need printer-sharing between VAX terminals (MicroVAX, for instance) and one Macintosh Plus using a LaserWriter IINT or IINTX, the simplest solution would be to use the one Macintosh Plus system as a terminal.

This can be accomplished through the use of one of the many terminal emulators available. This also prevents you from having to install a network for just one machine's needs.

Another possibility is to upload PostScript output files from the Macintosh to the MicroVAX and have the VAX print them. These files can be generated by holding down the Command and 'k' keys when printing using the LaserWriter drivers. A disk file is then generated instead of actually printing to a LaserWriter.

A third possibility is installing an Ethernet between the MicroVAX and a FastPath and connecting the FastPath and the Macintosh Plus together through an AppleTalk network. The MicroVAX would need to be running LaserWriter spooling software that would allow it to accept files over the network from the Macintosh Plus.

The drawback with such a setup is that users of WordPerfect on the MicroVAX might not be able to use the printer if the software on the MicroVAX is unable to accept print jobs from multiple (different) sources.

NuBus, MicroChannel, And EISA: Questions And Answers

=====

Article Created: 26 January 1989
Article Last Reviewed: 21 July 1992
Article Last Updated:

TOPIC -----

Here are some questions and answers about Apple's NuBus versus IBM's MicroChannel Architecture and the proposed Extended Industry Standard Architecture (EISA):

DISCUSSION -----

MULTIMASTERING

Q) How many coprocessor cards can NuBus support?

A) Any single NuBus card can be the Master (a card that initiates the addressing of another card) at any time. This action can be passed from card to card. Because of Apple's implementation of six slots, only six NuBus master cards can be supported in the Macintosh II.

NuBus itself can utilize an arbitrary number of slots, based on the designated size of each slot. The upper one-sixteenth of the total address space is available for slot space. This provides 256MB of addressing. Apple provides six slots of 1MB each in 24-bit mode. In the 32-bit mode, there are 16 possible slots on the Macintosh II, with an address space of 16MB each.

PERFORMANCE

Q) Can NuBus support processor speeds up to 25 MHz? 33 MHz? 45 MHz?

A) Cards can maintain their internal clock up to any possible speed. There are no set limitations for a card's internal clocks. Limitation are

imposed by NuBus transactions. NuBus is clocked at 10 MHz.

ADDRESS SPACE

Q) Is NuBus hardwired at 24 address lines?

A) NuBus is not hardwired at 24 address lines. It is a full 32-bit bus. The 24-bit addressing mode is a software-controlled mode imposed for compatibility with the 24-bit addressing System 6.

MEMORY

Q) What's the maximum amount of memory addressable through today's NuBus?

A) The maximum amount of memory addressable on the NuBus is 4 gigabytes. This is the total addressable range at 32 bits. On the Macintosh II, ROM space is reserved for 1MB of space. RAM is reserved for 1 gigabyte. Additionally, the NuBus slot address space includes a super slot space of 1.536 gigabytes allocated to the six slots for 256MB per slot and a slot space of 256MB allocated for 16 slots at 16MB each.

The breakdown is:

Memory: ROM, RAM, and slot space

ROM:	1MB
RAM:	1000MB
Super Slot:	1536MB
Slot:	256MB

Total:	2793MB

Q) How much memory can be added on a card or the motherboard?

A) The NuBus will access up to 16MB of RAM on a card in slot space and 256MB of RAM in Super Slot space. The maximum direct addressable range through the Macintosh OS is currently 1MB per card.

The full address range (up to 256MB) can be addressed by NuBus or by page flipping the memory on the card. The Macintosh II motherboard physically can connect 8MB. The maximum possible when looking at the NuBus and reserved memory addresses is 1 gigabyte.

DMA

Q) What are the DMA capabilities of NuBus?

A) DMA is not supported across NuBus.

NuBus-to-Macintosh II Address Mapping

24-bit Addresses from MC68020	32-bit Addresses from MC68020	NuBus Addresses	Used To Access Macintosh II Sys
\$xx00 0000 to \$xx7F FFFF	\$0000 0000 to \$007F FFFF	\$0000 0000 to \$007F FFFF	Present RAM
	\$0080 0000 to \$3FFF FFFF	\$0080 0000 to \$3FFF FFFF	Future RAM
\$xx80 0000 to \$xx8F FFFF	\$4000 0000 to \$4FFF FFFF	\$F080 0000 to \$F0FF FFFF	ROM (aliased)
\$xxF0 0000 to \$xxFF FFFF to	\$5000 0000 to \$5FFF FFFF	\$F000 0000 to \$F070 FFFF	I/O (aliased); do not access from a slot card
	\$6000 0000 to \$8FFF FFFF	\$60000 0000 to \$8FFF FFFF	Presently unused
	\$9000 0000 to \$EFFF FFFF	\$9000 0000 to \$EFFF FFFF	Super slot space, slots \$9 to \$E
\$xxF0 0000 to \$xxFF FFFF	\$F000 0000 to \$F0FF FFFF	\$F000 0000 to \$F0FF FFFF	Slot \$0 (Macintosh system)
	\$F100 0000 to \$F8FF FFFF	\$F100 0000 to \$F8FF FFFF	Presently unused
\$xxs0 0000 to \$xxsF FFFF	\$Fs00 0000 to \$FsFF FFFF or \$Fs10 0000 to \$FsFF FFFF	\$Fs00 0000 to \$FsFF FFFF or \$Fs10 0000 to \$FsFF FFFF	Slot space, slot s (s in range \$9-\$E)
	\$FF00 0000 to \$FFFF FFFF to	\$FF00 0000 to \$FFFF FFFF	Presently unused

FOR MORE INFORMATION

Check "Designing Cards and Drivers for Macintosh II and Macintosh SE" (ISBN #0-201-19256-X) from Addison-Wesley; mechanical drawing of cards and connectors available from APDA; and NuBus patent licenses from Texas Instruments, Inc.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Apple II System Disk 3.0: Requires MouseText, 128K Memory

Revised: 4/11/91
Security: Everyone

Apple II System Disk 3.0: Requires MouseText, 128K Memory

=====

This article last reviewed: 20 January 1989

Here are some questions and answers about Apple II System Disk 3.0 for the Apple IIe and Apple IIc:

- Q) Will this disk operate on an unenhanced Apple IIe?
- A) System Disk v3.0 uses an AppleWorks-style interface, and this requires the availability of MouseText characters, which do NOT exist in an unenhanced Apple IIe. The program may also use some of the additional 27 instructions available only in the 65C02 CPU.

- Q) What is the latest version of System software that will operate with an unenhanced Apple IIe?

- A) System Utilities Version v2.1.1 will work on an unenhanced Apple IIe, but even that requires some MouseText characters, and will show an abnormal display -- for example, Upper Case Inverse Capital S characters instead of straight horizontal lines.

However, the program runs properly in spite of this display anomaly. System Utilities v2.1 does not use MouseText characters and should function normally on an unenhanced Apple IIe.

- Q) How much memory does the System Disk v3.0 require to operate?

- A) When booted on a 64K enhanced Apple IIe, the program gives an error message stating it requires 80-column text, and this indicates it requires 128K of memory.

Fax Machines: CCITT Group 2 and Group 3 Explained (9/94)

Article Created: 20 January 1989
Article Reviewed/Updated: 7 September 1994

TOPIC -----

This article describes CCITT Group 2 and Group 3.

DISCUSSION -----

International Telephone and Telegraph Consultative Committee (CCITT) uses "Group" to designate the protocols used for facsimile transmission and reception. The "Group" protocol involves speed of transmission, height of a scan line, modulation/demodulation technique, encoding/decoding technique (if any), and various other parameters concerning communication between two Fax machines.

The primary difference between Group 2 and Group 3 concerns encoding/decoding.

Group 2 machines exploit bandwidth compression techniques to achieve reduced transmission times, when compared to Group 1 machines (Group 1 machines have long since disappeared). Bandwidth compression in this context includes encoding and/or vestigial sideband working but excludes processing of the document signal to reduce redundancy.

The encoding/decoding involved in transmission uses the positive/negative cycles of the square wave carrier to denote white/black pixels.

Group 3 machines incorporate a means for reducing the redundant information in the document signal prior to the modulation process. This allows for reduced transmission times compared to Group 2 machines. The Fax machine may incorporate bandwidth compression of the line signal.

The encoding/decoding technique used with Group 3 machines sends an encoded message when encountering lengths of white/black pixels (redundant information). This encoded message indicates the number of white or black pixels.

Apple II Language Card Changes

Revised: 9/18/89
Security: Everyone

Apple II Language Card Changes

=====

This article last reviewed: 17 March 1989

Effective immediately, Apple is substituting a different Apple II Language Card for the original one. The new card is smaller and no longer includes the connector that plugs into the RAM socket. It also does not contain the Autostart ROM. Now, when Apple II Language Cards are exchanged, Apple will include a 16K RAM chip with the replacement module.

- When you install a new Language Card into an Apple II or Apple II+ system, you need to install the 16K RAM chip into the vacant RAM socket on the main logic board.
- In the unlikely event that customers do not already have the Autostart ROM in their Apple II systems, they will need to purchase one for you to install in location F8 on the main logic board. The Autostart ROM (p/n 342-0020) can be ordered from the price pages.
- Refer to the Apple II Family Technical Procedures for instructions on installing Autostart ROMs and the 16K RAM.

The new Apple II Language Card is available from the price pages under the same part number as the old card. The new card is available as an Exchange Module only. When you return a language card to Apple for exchange, a new language card will be returned to you.

INSTALLATION

WARNING: Be sure the power is off before installing or removing any modules or components, or before connecting or disconnecting any peripheral devices. Failure to do so may result in damage to the computer, module, components, and/or peripheral.

Remember to follow basic ESD precautions when installing, removing, or troubleshooting modules.

- 1) Insert the Language Card into slot 0, component side facing away from power supply.
- 2) Insert a 16K RAM chip (p/n 334-0002) at location E3 on the motherboard. (Location E3 is in the left rear corner of the outlined memory area and was used for the cable header on the old Language Card.

Apple II Standard Computers without Autostart ROM on Motherboard:

- 1) Replace the Monitor ROM (p/n 342-0004) with an Autostart ROM (p/n 342-0020) at location F8-ROM on the motherboard.

TESTING

The new language card can be tested with your existing Apple II Product Diagnostics Disk.

- 1) Install the new Language Card in slot 0. Ensure that you've inserted a RAM at location E3 and that the motherboard F8 ROM is p/n 342-0020.
- 2) Start up the Apple II Product Diagnostics Disk.
- 3) Press the <ESC> key to move the cursor to the CARD TESTS line on the main menu, then press <RETURN>.
- 4) Press the <ESC> key to move the cursor to the LANGUAGE CARD line on the CARD test menu, then press <RETURN>.

If any RAM is highlighted in inverse video, replace the Language Card. If any of the status states are bad, then replace the Language Card. If the message "NO ERRORS ENCOUNTERED" appears, then the ROM at Location F8 is good. If the message "CAN NOT MATCH CODE" appears, then the ROM at F8 is bad and must be replaced.

Motherboard RAM Test

Perform the Motherboard RAM test to ensure that the RAM at location E3 is good.

- 5) Use the <ESC> key to move the cursor to the MOTHERBOARD RAM TEST line on the main test menu, then press <RETURN>.
- 6) Press <RETURN> to start the test.
- 7) The test will end and the display will show any bad RAM in inverse video. If the display shows that the LANG CARD RAM is bad then replace the RAM at E3.

Apple 40SC Backs Up Files To 38.5MB

Revised: 9/29/90
Security: Everyone

Apple 40SC Backs Up Files To 38.5MB

=====

This article last reviewed: 20 January 1989

When doing a file backup, 38.5MB is the largest file that can be backed up using the Apple 40SC tape backup unit and Apple software.

An oversize (larger than 38.5 megabytes) file may not be backed up across multiple tapes. It is possible to back up an oversize file using a third-party utility, such as DiskFit from SuperMac Technologies.

HyperCard 2.3: Data Handling Limits (1/96)

Revised: 1/4/96
Security: Everyone

HyperCard 2.3: Data Handling Limits (1/96)

Article Created: 10 April 1989
Article Last Reviewed/Updated: 4 January 1996

TOPIC -----

What are some of the limits of HyperCard and its various components?

DISCUSSION -----

HyperCard's maximum limits are theoretical. In a practical situation, the actual limits may be less than, or sometimes greater than, the limits stated here and in the HyperCard documentation. This is due to the different levels of complexity possible in a stack. For example, HyperCard currently brings an entire card into memory at once, so the maximum size of a card is limited by available memory. It's possible that a card with a lot of extra text and long scripts, created while running HyperCard on a Macintosh with 2 megabytes of RAM, could not be opened on a Macintosh with 1 megabyte. The current useful size of a card (or background) is therefore between 50 and 100 kilobytes. The value represented by LONGINT is 2,147,483,647; the value represented by INTEGER is 32,767.

STACK LIMITS

Stack size: 512 megabytes
Minimum stack size: 4896 bytes
Maximum total number of bitmaps, cards, and backgrounds per stack: 16,777,216
Maximum stack name size: 31 characters
Maximum stack script size: 30,000 characters

BACKGROUND LIMITS

Background Size (bytes): LONGINT (limited by HC stack size; less than 100 kilobytes for practical use)
Minimum background size: 64 bytes
Maximum parts per background: Integer
Maximum total part size per background (bytes): LongInt

Maximum background name size: 31 characters
Maximum background script size: 30,000 characters

CARD LIMITS

Card size (bytes): LONGINT (limited by HC stack size; less than 100 kilobytes for practical use)
Maximum card size: 64 bytes
Maximum parts per card: INTEGER
Maximum total part size per card (bytes): LONGINT
Maximum total text size per card (bytes): LONGINT
Maximum card name size: 31 characters
Maximum card script size: 30,000 characters

PART (BUTTON OR FIELD) LIMITS

Part size (bytes): INTEGER (The sum of the other elements in the button or field must be less than the part size.)
Minimum overhead per part: 30 bytes
Maximum part name size: 31 characters
Maximum part text size: 30,000 characters
Maximum part script size: 30,000 characters

HYPERTALK LIMITS

Maximum nested REPEAT structures: 30
Maximum nested REPEAT structures: 32
Maximum active variables (all pending handlers): 512
Maximum size card name with GO command: 31 characters
Maximum variable name size: 31 characters
Maximum number format size: 31 characters
Maximum size of command with arguments: 254 characters
Maximum handler name size: 254 characters
Maximum script size: 30,000 characters
Maximum variable value size: Limited by available memory

Article Change History:
04 Jan 1996 - Added new limit information.

Security: Everyone

Apple Monitors Meet VDT Emissions and SWEDAC 2 Standards (8/94)

=====

Article Created: 26 January 1989
Article Reviewed/Updated: 8 September 1994

Apple meets all VDT emissions specifications required by the FDA.

The FDA has published a specification for ionizing radiation, CFR-21, and all VDTs (CRTs) sold by Apple meet this specification. Apple monitors do not exceed the radiation requirement called out by this specification.

The FDA specifications call for a maximum radiation of 0.5 mr/hr. Apple's monitor emissions are 0.05 mr/hr, or one-tenth of allowable standard.

In addition to the FDA's specification, all of Apple's current displays (including the Mac Classic) meet or exceed the strict internationally recognized standard for monitor ELF/VLF emissions--SWEDAC 2 (also known as MPR2).

Article Change History:

AppleShare Support: AppleCD SC And WORM Drives

=====

This article last reviewed: 26 January 1989

Currently, an AppleShare File Server requires that all drives (volumes) attached to the server support read AND write access. The one exception to this rule is the AppleCD SC, which is supported.

Since a WORM (Write Once, Read Many) drive does not allow true read and write access, it is not supported by AppleShare.

MPW Version 3.0: General Information

Revised: 3/23/89
Security: Everyone

MPW Version 3.0: General Information

=====

This article last reviewed: 31 January 1989

Macintosh Programmer's Workshop (MPW) 3.0 is available through the Apple Programmer's and Developer's Association (APDA).

MPW 3.0 features a new debugging tool, Symbolic Application Debugging Environment (SADE), and a project management system called "Projector".

SADE is an interactive debugger that works either at the processor or symbolic program source level. Projector is a collection of built-in MPW commands and windows that manages changes to all files (source, documentation, etc.) associated with a software project.

An Installer disk is included for installing MPW 3.0 from a set of diskettes.

(NOTE: The file configuration on these diskettes is different from previous releases. There are now duplicate folder names across the set of diskettes. Thus, dragging folders on to the hard disk from the diskettes may result in name conflicts.)

MPW 3.0 requires, at minimum, a Macintosh Plus, hard disk, and 2MB of RAM. The minimum System files required are found on System file version 6.0.2 or later. SADE requires MultiFinder and at least 2.5MB of RAM. (The recommended system configuration is a Macintosh II with 4MB or more of memory and an 80MB SCSI hard disk drive.)

MPW v3.0 contains current releases of the language products (MPW Assembler 3.0, MPW C 3.0, and MPW Pascal 3.0) have also been introduced. MPW C 3.0 is a completely new C compiler. It is largely compatible with MPW version 2.0, but there are some changes to the language, compiler options, new files, and Standard C Library and Macintosh Interface, which require modification of MPW 2.0 source code.

A script utility called CCvt is also provided to help convert MPW 2.0 source code headers and standards for functions using strings or points to the

MPW 3.0 convention.

Security: Everyone

Macintosh SE, II, IIX: Launching Guided Tours from Hard Disk

=====
Article Created: 22 March 1989
Article Last Reviewed: 8 July 1992
Article Last Updated: 8 July 1992

TOPIC -----

How does one use the Guided Tour from a hard disk?

DISCUSSION -----

You can use the Guided Tour from a hard disk on the Macintosh II, IIX or Macintosh SE as long as there is a minimum of 2MB of memory in the computer.

The Guided Tour disk has a modified System/Finder because the tour requires a minimum of 960K of memory to run. With a standard System/Finder installed on a 1MB system, there is not enough memory available. The modified system files -- which are smaller than the standard files -- allow a 1MB system to have the required 960K of memory available for the Guided Tour.

With a standard System and Finder installation and 2MB of memory, just copy the Tour Engine and all the tour files to a folder on the hard disk. If you want the Guided Tour to come up automatically on startup, then set the Set Startup option under the Special menu to the Tour Engine (if running System 6) or place an alias of the Tour Engine in the Startup Items folder inside the System Folder (if running System 7). Upon finishing the Guided Tour, the user is returned to the standard Finder Desktop.

Print Servers Provide Multiple Users, Not Necessarily Speed

Revised: 5/31/89
Security: Everyone

Print Servers Provide Multiple Users, Not Necessarily Speed

=====

This article last reviewed: 31 January 1989

The main reason for using the AppleShare Print Server is to allow many users to print documents at the same time. A print server reduces the waiting time by allowing several users to send documents to be printed simultaneously. When used with a LaserWriter, Postscript code is sent to the print server and then to the printer. The printer then processes this Postscript code to produce bit-map graphics at 300 dpi.

When printing to an AppleTalk ImageWriter, the computer creates and sends the bit-map image to the printer. Creating this bit map takes processing time from the computer. Because the computer must spend time creating the bit map, you will not see a major difference in the amount of time it takes to send the data to the printer or the spooler. When printing directly to a printer, the print driver runs at an even speed with the printer, due to data transmission speeds.

When connected over AppleTalk, the network runs faster than 19,000 or 9600 baud, but the driver has not been optimized for speed. It keeps up with the speed of the printer. Some times, the computer is waiting for the printer to finish printing a line; other times, the printer is waiting for the computer to send and process the line. This is why the 32K option card is not recommended for Macintosh users.

Macintosh Scrapbook And 24-Bit Images

Revised: 6/16/92
Security: Everyone

Macintosh Scrapbook And 24-Bit Images

=====
Article Created: 9 February 1989
Article Last Reviewed: 28 May 1992
Article Last Updated:

TOPIC -----

Can I paste a 24-bit graphic into the Scrapbook from an application without losing any of the detail or color depth?

DISCUSSION -----

The Macintosh Scrapbook can handle 24-bit images. The application from which the image is being copied must support copy and paste commands for the scrapbook. The application must place the image in a PICT2 file format, which includes parameters for describing the image (8-bit, 24-bit, chunky, planar, and so on).

A problem occurs, however, when displaying a 24-bit image on an 8-bit video card and/or in an 8-bit graphics program. The image colors will be incorrect, because they are set for 24 bits, but the image will continue to be stored as a 24-bit image. For example, one possible outcome of a 24-bit RasterOps image paste to 8-bit Pixel Paint is a blue image. This is because three 8-bit red, green, and blue transfers are sent to the video card. The last image transfer is blue, so a Macintosh II video card will only show the blue portion of the image.

The image also may not display correctly when pasting to different 24-bit displays, because the implementation of 24-bit color differs from video card to video card.

25-Pin SCSI Terminator: How To Build

Revised: 4/11/91
Security: Everyone

25-Pin SCSI Terminator: How To Build

=====

This article last reviewed: 31 January 1989

Here is how you can make a 25-pin terminator (a rarely-needed commodity).
Pinouts for the SCSI port are as follows:

Pin No. -----	Signal Name -----	Description -----
1	REQ/	Request
2	MSG/	Message
3	I/O/	Input/Output
4	RESET/	Reset
5	ACK/	Acknowledge
6	BSY/	Busy
7	GROUND	Signal Ground
8	DB0/	Data Bit 0
9	GROUND	Signal Ground
10	DB3/	Data Bit 3
11	DB5/	Data Bit 5
12	DB6/	Data Bit 6
13	DB7/	Data Bit 7

14	GROUND	Signal Ground
15	C/D/	Control/Data
16	GROUND	Signal Ground
17	ATN/	Attention
18	GROUND	Signal Ground
19	SEL/	Select
20	DBP/	Data Parity
21	DB1/	Data Bit 1
22	DB2/	Data Bit 2
23	DB4/	Data Bit 4
24	GROUND	Signal Ground
25	TERMPWR	+5 volts

Inside the Apple SCSI Terminator each signal line (ends with "/") is connected to TERMPWR through a 220-ohm resistor and is also connected to GROUND through a 330-ohm resistor.

The obvious tradeoff here is cost versus time to build this terminator. It would seem that size is also an issue; this is a lot of resistors and solder

joints to deal with.

However, if someone needs it, and where appearance is not an issue and energy is in abundance, this is a solution.

Q And A: File Server Applications And Local Applications

=====

This article last reviewed: 1 February 1989

Here are some questions and answers about using applications (MacWrite is the example here) over a LocalTalk network with an AppleShare file server, versus having individual copies of the application on the users' hard disks.

Q) If a user double-clicks on one of the MacWrite documents on the server, which application will be opened: the MacWrite on the server or the MacWrite on the user's hard disk?

A) The Macintosh OS always chooses an application residing on a local disk over a server-based application. Given the choice between an application on a local hard disk and one on a floppy drive, it will choose the hard disk.

Q) What happens if more than one user double clicks on the same MacWrite document at the same time?

A) Only one user will be able to access the file. The first one to try to open the file -- even if that primacy is only a matter of nanoseconds -- will be victorious. All successive attempts will result in a "file locked or in use" error message.

Q) Should you launch the application on your hard disk, then open the document on the server, or should you use the program on the server when you work with a document on the server?

A) Apple recommends that unless the application is designed for multilaunch use, have local copies of the application for each user and keep documents on the server.

Apple IIGS: Use FakeMouse To Move Cursor

=====

This article last reviewed: 1 February 1989

If you are programming for the Apple IIGS, and want to write a demo program that moves the mouse automatically across the screen, you have probably discovered that when you can use the POSMOUSE command to move the cursor position, but that when it moves to the new position it disappears. The only way to get the cursor to reappear is to move the mouse.

Rather than using PosMouse, you should use FakeMouse as described on pages 7-34 of the Apple IIGS ToolBox Reference Manual, Volume 1 (ISBN #0-201-17746-3).

AppleShare PC: PostScript Print Speed

=====

This article last reviewed: 15 December 1988

If you are using AppleShare PC and find that your LaserWriter takes about three to four minutes to print a single page from WordPerfect, your problem may be that WordPerfect and the DOS "Copy" command are not immediately sending an "end-of-document" code to the LaserWriter.

Without this "end-of-document" code, the LaserWriter has no way of knowing it has received all of the output from the computer. This causes the LaserWriter to wait until it times out. When it times out, it assumes the file has been completely received and prints it. This timeout is generally two to three minutes, but can be changed with a PostScript program.

AppleShare PC has an option in the Chooser that allows you to set the number of seconds the LPT port must be inactive after a print job before an "end-of-document" code is automatically sent.

You also can send an "end-of-document" code to the LaserWriter immediately after printing by typing Ctrl-Alt-F10.

Ported MS-DOS Files: How To Set TYPE And CREATOR

Revised: 3/23/89
Security: Everyone

Ported MS-DOS Files: How To Set TYPE And CREATOR

=====

This article last reviewed: 15 December 1988

Some users have had trouble with Apple File Exchange when using AppleShare PC and a PC drive to translate a file. During an ordinary text translation from the PC drive, they can translate a file across and generate a Macintosh file with a type of TEXT and a creator of MDOS, which can be seen by an ordinary (non-shift-Option) open file dialog by Microsoft Word (or a similar application).

However, if a PC on an AppleShare network puts the file on a server, and they pull it down with a Macintosh and try the translation, they get a file of type crlf and a creator of MDOS, which remains unseen to an ordinary open file dialog in Microsoft Word. This makes it impossible to translate it to type TEXT.

In the Special menu of the AppleShare PC DA, there is an option called Extension Mapping. (Early documentation of AppleShare PC had this option incorrectly listed in the Assignments menu.) This option automatically sets the Macintosh desktop attributes, TYPE and CREATOR of an MS-DOS file, based on its three-letter name suffix. For example, files created with a .DOC suffix from Microsoft Word on a DOS system can automatically appear as a Macintosh Microsoft Word icon on AppleShare; or .WKS files from Lotus 1-2-3 can appear as Excel icons. These files, though created directly from an MS-DOS application, can be opened directly from Macintosh applications.

If you are porting ASCII text between the two environments, be sure that DOS-Text is not selected in the Extension Mapping for .TXT files. This appends a Carriage Return and Line Feed (crlf) on the end of each line and gives it a type of crlf and a creator of MDOS (sound familiar?). Macintosh word processing applications expect to see a type of TEXT for ASCII files.

AppleShare PC DA Cannot Be Loaded Into Expanded Memory

Revised: 5/24/89
Security: Everyone

AppleShare PC DA Cannot Be Loaded Into Expanded Memory

=====

This article last reviewed: 10 January 1989

The AppleShare PC Desk Accessory cannot be installed into expanded memory. However, if you have expanded memory, and if the Desk Accessory is memory-resident, the window buffers make use of expanded memory.

If you are operating in text mode, then the approximately 2K large window buffer might be placed into that expanded memory space. If you are in graphics mode, it might be as large as 16K.

If memory is at a premium, you may not want to make the program memory-resident. You can then use the Desk Accessory by running the program at the DOS prompt.

NOTE: AppleShare PC 1.2 will not run under DOS 4.0 or 4.0.1; however, the driver WILL work, enabling you to continue to use the printer services.)

LaserWriter: How To Check For Laser Prep Dictionary

=====

This article last reviewed: 12 July 1989

If you want to query the LaserWriter to see if the "Laser Prep" information exists (if, for instance, you are using the LaserPrep dictionary) before sending a PostScript file, use the following procedure.

The Laser Prep dictionary, when in the LaserWriter, is called "md". The following PostScript command pushes the Boolean "false" onto the stack if the dictionary is not found. If the dictionary is found, the dictionary object and the Boolean "true" is pushed onto the stack:

```
/md where
```

The following command immediately returns a "1" if the Laser Prep dictionary is present and a "0" if it is not:

```
/md where{/md get /av get cvi 68 eq{(1)}{(2)}ifelse}{(0)}ifelse = flush
```

AppleScan PICT Format

Revised: 5/24/89
Security: Everyone

AppleScan PICT Format

=====

This article last reviewed: 5 January 1989

This article describes PICT file format as saved by AppleScan. AppleScan uses the standard PICT file format, in which the first 512 bytes carry application-specific header information. Depending on the application and how it treats this header information, some applications may have problems reading or interpreting the file information. The rest of this article contains a Pascal Type declaration and descriptions of each parameter.

Pascal Type Declaration

The following Pascal TYPE declarations define the format of the first block (block #0) of AppleScan PICT files (creator "APSC" and file type "PICT"). Subsequent blocks contain the actual version 2 PICT, as specified in "Inside Macintosh Volume V, Color QuickDraw."

```
str17 = string[17];
```

```
cnbs = RECORD
```

```
contrast: signedByte
```

```
brightness: signedByte
```

```
hpat = array [1..16] of signedByte;
```

```
SaveScanInfo = RECORD
```

```
Version: INTEGER
```

```
Reduction: INTEGER
```

```
Composition: INTEGER
```

```
Threshold: INTEGER
```

```
ContBriteName: str17
```

```
ContBrite: cnbs
```

```
AutoAdjust: BOOLEAN
```

```
HalftoneName: str17
```

```
HalftonePattern: hPat
```

```
Graymap: INTEGER
```

```
PictHeader = RECORD
StdHeader: PACKED ARRAY [1..230] OF SignedByte;
SaveScanInfo: SaveScanInfo; (* 66 bytes *)
Filler: PACKED ARRAY [1..216] OF SignedByte;
```

Parameter Descriptions

The StdHeader and fFiller fields are all zeroes.

The Version field is the AppleScan version number (for example, 102 = 1.0.2).

The Reduction field is the reduction percentage.

The Composition field is the composition encoded as follows:

```
0 = Line Art
1 = Halftone
2 = Grayscale
```

The Threshold field is the threshold value.

The ContBriteName field is the name of the Contrast & Brightness setting.

The ContBrite field contains the values of the Contrast and Brightness settings.

The AutoAdjust field is the Automatic Adjustment setting.

The HalftoneName field is the name of the Halftone setting.

The HalftonePattern field contains the values of the halftone pattern matrix, stored in row-and-column order (for example):

```
0  1  2  3
4  5  6  7      is stored as 0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15).
8  9 10 11
12 13 14 15
```

The Graymap field is the Graymap setting encoded as follows:

```
0 = Light Detail
1 = Normal Detail
2 = Dark Detail
```

Apple IIC Plus: Changing Clock Speed

Revised: 3/23/89
Security: Everyone

Apple IIC Plus: Changing Clock Speed

=====

This article last reviewed: 6 January 1989

Early versions of Apple IIC Plus Owner's Guide (page 19) explain the sequence for changing the Apple IIC Plus from 4 MHz to 1 MHz. In the following examples, the COMMAND key is the same as the OPEN-APPLE key. The keystroke sequence is:

```
(press and hold) ESCAPE-COMMAND-CONTROL
(press and release) RESET
(when 'Normal' appears, release) ESCAPE
(release) COMMAND-CONTROL
```

However, the early manuals do not document the method of returning to 4 MHz. The keystroke sequence is:

```
(press and hold) COMMAND-CONTROL
(press and release) RESET
(release) COMMAND-CONTROL
```

Both of the above sequences do a warm boot of the computer. The difference is that the ESCAPE key in the first sequence tells the Apple IIC Plus to use the 1 MHz (Normal) speed.

Here are additional techniques for changing the speed when you start the computer:

Entering the 1 MHz mode at Startup

Powering on with the Escape key held down places the Apple IIC Plus in Normal mode (1 MHz). The word "Normal" appears in the middle of the second line of a screen full of reverse "@" and checkerboard cursors. Pay close attention to the screen: it clears quickly and the "Apple IIC +" screen appears.

To enter the 4 MHz mode at Startup

Powering on with no keys pressed places the Apple IIc Plus in the faster mode.

One anomaly can occur during the keystroke process. In Applesoft, the Escape key toggles between cursor movement mode and text entry mode. The use of the Escape key in the above key sequences can have the side effect of toggling the cursor movement/text entry modes. If the cursor has the "+" sign in the center, you are in cursor movement mode. To return to text entry mode, press the Escape key (actually, any key) once.

Apple Macintosh Portrait Display:Description (Discontinued)

Revised: 6/6/94
Security: Everyone

Apple Macintosh Portrait Display:Description (Discontinued)

=====

The Apple Macintosh Portrait Display is a high-resolution, 15-inch, monochrome monitor for the Apple Macintosh II personal computer family. It's ideal for work with desktop publishing, word processing, and general productivity applications because it can display one full page of text and graphics. The Portrait Display shows a complete page of information as it will appear in print. This makes it easy to preview, edit, and add text or graphics and minimizes scrolling.

Users of the Portrait Display will find that word processing and page layout will be more accurate and much more efficient.

The Apple Macintosh Portrait Display uses a flatter screen and higher refresh rate than many other displays, which minimize eyestrain and ensure that the image on the screen is sharp and focused.

The Portrait Display may be configured with the Macintosh II, Macintosh IIX, and Macintosh IICx computers. The Portrait Display uses the Macintosh II Portrait Display Video Card. This card is specific to the Portrait Display.

The Macintosh Portrait Display introduces Apple Desktop Bus connectors in the monitor. These three ADB connections allow a cable to be attached to a remote Macintosh main unit and to the back of the Portrait Display while providing connection points for the mouse and keyboard ADB cables.

Apple II Video Overlay Card: Connectors (11/96)

Revised: 11/21/96
Security: Everyone

Apple II Video Overlay Card: Connectors (11/96)

Article Created: 03 June 1988
Article Reviewed/Updated: 15 November 1996

TOPIC -----

The Apple II Video Overlay card can receive video signals from any number of sources: VCR, Video camera, Video disc player, even cable television. Because there are numerous connectors associated with these video sources, it is necessary to clarify the connection schemes as they relate to the Apple II Video Overlay Card.

DISCUSSION -----

Connection Schemes
=====

RGB Connections

Any RGB monitor must connected to the DB-15 connector on the card. The AppleColor RGB Monitor connects directly with the DB-15 cable that ships with the monitor.

If you are using another RGB monitor, you must build the correct cable. The Apple II Video Overlay Card DB-15 connector has the same pinout as the AppleColor RGB Monitor. For more information on this reference Tech Info Library article "AppleColor RGB Monitor input connector: Pinouts". It is a simple matter to construct the rest of the cable, using the pinout supplied with the third-party monitor.

External Video Source Connections

To connect external video sources to the Apple II Video Overlay Card, at least one end of the cable must have an RCA phono plug. This end will connect to the overlay card. Normally, consumer electronics video sources will have an RCA connector for direct video output. To ensure top quality video reproduction, use

gold-plated RCA connectors.

BNC-Style Connections

It is normal for some high-end professional video equipment to have BNC-style connectors for the video output. If this is the case, an adapter must be used to convert the BNC connector to RCA phono type for connection to the card. These are readily available at most electronics stores.

RF Connections (also known as an "F" connector)

If your video equipment uses an RF cable (also known as an "F" connector), it cannot be directly connected to the Apple II Video Overlay Card. You must connect this cable to a VCR first, then connect the VCR to the overlay card, using an RCA phono type cable.

S-VHS Information

It is not possible to feed an S-VHS (Super VHS) signal into the overlay card. If your S-VHS equipment has RCA phono jacks, cables can be connected from these jacks to the card, but the overlays resulting from this connection will have the resolution of standard VHS, not S-VHS.

Apple II Video Overlay Card: Using Key Colors (11/96)

Revised: 11/21/96
Security: Everyone

Apple II Video Overlay Card: Using Key Colors (11/96)

=====

Article Created: 03 April 89
Article Reviewed/Updated: 18 November 1996

TOPIC -----

This article discusses how to use the Key Color selection of the Video Overlay Card.

DISCUSSION -----

Creating an overlay with the Apple II Video Overlay Card requires selection of a control color, called Key Color.

The VideoMix software treats the Key Color differently from the other colors. All colors not designated as the Key Color are treated as a group and are called non-Key colors.

For example, if the Key Color is Black, the video input signal will show through only where black is displayed on the screen. Where any other color is shown, the video will not show through and those areas will be showing the computer generated graphic. This would be the display, assuming VideoMix is set for 100% Key and 0% non-Key. By moving the sliders within VideoMix, these proportions can be changed to suit the user.

There are two methods for selecting the Key Color, select from Screen, and select from the color palette.

Selecting from the color palette allows selection of the Key Color from a palette of sixteen different colors. Use the mouse (Apple IIGS), or the arrow keys (Apple IIe), to select a color rectangle from the palette.

The other method is to use the option Select From Screen. An "X" appears in the box, and a hand with a pointing finger replaces the arrow cursor on the screen. With the hand cursor in the computer graphics area of the screen, click on the color of your choice. This becomes the Key Color.

Apple IIGS Note

The Apple IIGS can display graphics in one of two modes: 320 mode or 640 mode. In 320 mode, the computer can display sixteen pure colors. In 640 mode, it can display only two true colors: black and white. All other colors are blended colors formed by a process known as dithering. Dithered colors are formed by displaying two colors in adjacent pixels. Because the pixels are so small and close together, your eye perceives them as a single color. Light blue, for example, is formed by adjacent blue and white pixels.

When a dithered color is picked, the Key Color is the color of the pixel you happened to click on. If you picked the light blue color, the key color could be either blue or white.

Using dithered colors for your Key Color can produce some interesting, and sometimes unexpected, translucence effects in your overlay. These effects, while attractive, may not be completely reproducible. To avoid this, it would better to have your computer in 320 mode when making overlays. If you wish to use 640 mode, it is best to use black or white as your Key Color.

Apple II Video Overlay Card: Configurations (11/96)

Revised: 11/21/96
Security: Everyone

Apple II Video Overlay Card: Configurations (11/96)

=====

Article Created: 03 April 89
Article Reviewed/Updated: 18 November 1996

TOPIC -----

Listed below are several possible configurations using the Video Overlay Card.

DISCUSSION -----

Depending on how sophisticated a user wishes to be, and what the user wishes to accomplish, there are numerous possibilities for connecting monitors and other video equipment, to the Apple II Video Overlay Card. A setup could be as simple as a VCR, an Apple IIGS, and a single monitor; or as complicated as a videodisc player with a composite monitor, an Apple IIGS with RGB and a composite monitor, and a VCR with a composite monitor.

Typical Configuration

A typical configuration might be a VCR or video camera, for a video source, an Apple IIe (or Apple IIGS) with the Overlay card and VideoMix software installed, and a RGB monitor. This configuration would allow creation of overlays for direct viewing only. The addition of a second VCR would permit recording of the overlays created. If a composite monitor were connected to the output of the Overlay Card, the picture displayed there would be representative of what is being recorded on the VCR.

High-end Configuration

A high-end configuration might include the connection of an interactive video source, which would then display selected video sequences, as directed by the computer, while the program would automatically provide the proper window for the resulting video input. This setup would require the connection of the device control cable from the external device to the serial port on the computer.

Apple II Video Overlay Card: Features (11/96)

=====

Article Created: 04 March 1996
Article Reviewed/Updated: 18 November 1996

TOPIC -----

This article discusses the features of the Apple II Video Overlay Card.

DISCUSSION -----

Genlock circuitry

-
- Synchronizes the Apple II timing to external video timing.
 - Allows a user to superimpose Apple II graphics on top of an external video signal for titling or annotating video material.

RGB and Composite Outputs

Allows a user to simultaneously view overlays on an AppleColor Composite or RGB monitor while recording the overlay to a VCR.

Apple IIGS Graphics Chip Set

-
- Allows the video overlay card to display standard graphics when not producing overlays.
 - Improves composite video output by re-generating the video output signal from the computer.
 - Broadcast-quality video output.
 - Allows a user to use the overlay card in a professional broadcast environment (no degradation of video quality when passed through the overlay card).

VideoMix Software

Allows

- software control of the overlay card's functions.
- choice of key color (color which is transparent to the video signal), set the video/graphic mix, and adjust the color/tint of the RGB video.
- Apple IIe and Apple IIGS compatibility
- use of the overlay card with existing hardware and the extensive library of Apple II software.

Apple II Video Overlay Card: Tips (11/96)

Revised: 11/21/96
Security: Everyone

Apple II Video Overlay Card: Tips (11/96)

Article Created: 03 April 89
Article Reviewed/Updated: 18 November 1996

TOPIC -----

Here are some helpful tips and hints for using the Apple II Video Overlay card.

DISCUSSION -----

As you plan your video presentation, think about how the overlay will enhance your presentation. Do you want to include:

- Opening title and closing credits?
- Highlight information presented in the video?
- Dazzle the audience with special effects?

Planning For Computer Graphics

Try to determine where the computer graphics would be useful only where appropriate. You may find yourself overusing computer graphics. Consider whether you should highlight your video with computer graphics, narration, or a combination. Your overlays will be more effective if you use them judiciously.

Decide on a workable design for your graphics, and use it consistently throughout your presentation. For example, always use the same font for the text, the same colors for the graphic elements, such as line and boxes, and the same kind of special effects. Consistent use of computer graphics will make your presentation seem more unified and easier to follow.

Use high-quality video equipment and software that allows high resolution graphics. Clean the heads on your VCR if you haven't cleaned them lately. The better the video equipment and computer images, the better your overlays will look.

When shooting a video for an overlay, try to anticipate where your graphics will

fit into the shot and leave enough space for them. For example, if you plan to superimpose someone's name below a close-up of their face, leave enough room in the lower third of the screen. Treat the graphics as an integral part of the composition, not as an afterthought.

Designing For The Screen

Keep it simple, don't try to cram too much into a single overlay. If your video has lots of motion, use simple graphics. If your graphics are complex, consider using a still scene for the video portion.

Limit the information in each overlay to one or two points. Presenting too many facts in one overlay will not help the viewers remember them. Television viewers may not be able to flip back to review something they missed.

Use readable fonts for text. Bold, simple fonts seem crisp and are easily read on the screen. The color of your text should contrast with the video colors. If you plan to record the overlay, make the text at least 16 point.

Special Considerations for Composite Video

Avoid using computer graphics that are extremely bright. If the colors in your graphics are too intense, especially if they are hot colors such as bright red, the graphics may appear to vibrate along the edges. You can correct the problem by using a less intense color, like off-white instead of white. You can also reduce the intensity of a color by allowing some of the video image to blend in, using VideoMix.

If you are recording your overlays, view them on a composite monitor or a television.

Colors displayed on an RGB monitor are more stable than colors displayed on a composite monitor as they are less likely to shimmer or bleed into another color. If you are recording your overlays on tape, a composite monitor or a television will show you a better representation of the overlay's appearance during playback. By viewing your overlays this way, without an RGB monitor, you will be better able to see, and correct, problems before they are recorded on the videotape.

Apple II Video Overlay Card: Product Description (11/96)

Revised: 11/21/96
Security: Everyone

Apple II Video Overlay Card: Product Description (11/96)

Article Created: 03 April 89
Article Reviewed/Updated: 18 November 1996

TOPIC -----

Below is a description of the Apple II Video Overlay Card. This product has been discontinued and is no longer available from Apple.

DISCUSSION -----

The Apple II Video Overlay Card product, for the Apple IIe and Apple IIGS, includes an interface card and VideoMix software.

When in operation, the overlay appears as a computer image on top of a video image. The video image can be from any external video source: video tape, video disc, cable television, or video camera and the image can be shown on either a composite or RGB monitor. The NTSC signal output from the overlay card is of broadcast quality and can be recorded on a VCR.

The Apple II Video Overlay Card brings previously expensive genlock capabilities to the Apple II family of computers, and creates new possibilities for learning and creativity.

The overlay card has a complete, though modified, Apple IIGS graphics subsystem (Mega II, VGC, and supporting circuitry), which provides genlock and overlay capabilities, as well as improved composite video output. With a proper NTSC signal presented to the card, an FCC-legal output is supplied from the card, therefore the card is usable in professional broadcast environments.

After genlocking to the incoming signal, the overlay card determines which pixels will be video and which will be graphics, or if there will be combinations. These combinations are selected by way of the VideoMix software, which sets up the card for the desired mix of graphics and video. The user chooses a key color (the color that is transparent to the incoming video and is treated separately from the other colors), and what the video/graphic mix will be. VideoMix also allows the user to adjust the tint and color of the RGB video,

as on a color television. The user can also choose a color from the screen to be the key color.

Because the overlay card is a completely independent subsystem, it functions with any existing Apple II painting, drawing, and animation software -- these being the more relevant products conducive to creating overlays. The overlay card works with virtually all Apple II software.

32-Bit QuickDraw Information (12/95)

Revised: 12/6/95
Security: Everyone

32-Bit QuickDraw Information (12/95)

Article Created: 18 April 1989
Article Reviewed/Updated: 6 December 1995

TOPIC -----

This article defines 32-Bit QuickDraw, its components, and hardware requirements.

DISCUSSION -----

32-Bit QuickDraw is a collection of extensions to Color QuickDraw. It is also called "Full Color QuickDraw (FCQD)," but not "24-Bit QuickDraw." 32-Bit QuickDraw supports three modes.

- The first is the standard Color LookUp Table (CLUT) mode -- the method used by standard Color QuickDraw. This mode supports 1, 2, 4 and 8 bit colors.

The second and third modes use direct RGB values instead of CLUTs.

- The first of these two modes supports 16-bit direct color values (only the first 15 bits are significant).
- The second supports 32-bit direct color values (only the first 24 bits are significant).

The key features of 32-Bit QuickDraw include:

- Support for very large frame buffers
32-bit addressing of graphics devices
- Support for "Direct" Devices
Pixel values directly specify a color for "Direct" devices, so CLUTs are not used.
- Up to 16 million colors per pixel.

Color values contain up to 8 bits for each of the three RGB direct components, with 8 bits of padding, resulting in a maximum of 24 significant bits out of 32. The two direct RGB value frames supported by 32-Bit QuickDraw are these:

32-BIT DIRECT RGB VALUE FRAME: 00000000 RRRRRRRR GGGGGGGG BBBBBBBB

16-BIT DIRECT RGB VALUE FRAME: 0 RRRRRR GGGGG BBBB

- Extensions to the PICT file format
Support for up to 32 bits per pixel (up to 24 of which are significant)

Components for System 7 or later

32-Bit QuickDraw is integrated in System 7, and the 32-Bit QuickDraw INIT is no longer needed to get the benefits of 32-Bit QuickDraw. The System 7 Installer will delete the old 32-Bit QuickDraw INIT from your System Folder during installation.

Components for System 6.0.x

32-Bit QuickDraw files consist of the following and are found in the System Folder:

- General control panel, a version that fixes a desktop pattern editor bug.
- Monitors control panel, a version that recognizes direct devices and lets the user control them.
- 32-Bit QuickDraw INIT, a file containing the patches to Color QuickDraw and a version of the Slot and Palette Manager. This file is not an INIT. However, this file uses a startup-file mechanism included in Macintosh System Software, starting with version 6.0.3. This mechanism was created specifically for 32-Bit QuickDraw.
- LaserWriter 6.0 includes three files: LaserWriter, LaserPrep, and PrintMonitor. They support color PostScript, printing in gray scale, full 32-bit addressing, and double-byte PostScript (such as Kanji).
- LaserWriter 7.0 only has 2 files: LaserWriter and PrintMonitor.

Once you have put all these files into the System Folder, the computer must be restarted. Once 32-Bit QuickDraw is installed, the Finder presents a multi-colored icon for the 32-Bit QuickDraw file. The presence of this icon shows that 32-Bit QuickDraw is running.

NOTE: Those who want to print to a LaserWriter initialized with the LaserPrep file must update their systems to at least System Software v 6.0.3 and to the LaserWriter 6.0 resources. If your hardware does not support 32-Bit QuickDraw, you need not install the new Monitors, General, or 32-Bit QuickDraw files.

Hardware Requirements

To get the full benefits of 32-Bit QuickDraw, you must have a direct device video card. In other words, the video card must be able to accept direct color values, instead of receiving a color value that is an index number into a CLUT. Monitors that support 32-Bit QuickDraw are dictated by the available 32-Bit video cards.

However, for those who are not using a direct-device display, 32-bit QuickDraw lets software create 32-bit images off screen. This means that programs using 32-Bit QuickDraw to its full potential can actually save 32-bit images, regardless of what the actual hardware can display.

Software Compatibility

32-Bit QuickDraw does not add or eliminate any QuickDraw procedure or function calls. Applications that make standard Color QuickDraw calls should have no problems. However, applications that do any of the following things may have problems with 32-Bit QuickDraw:

- Draw directly to the screen
- Fail to put values in all of the necessary fields in the pixmap and newGDevice records
- Manually clone gDevice pixmaps
- Assume that a pixmap has a CLUT

Article Change History:

06 Dec 1995 - Updated with System 7 or later information.

AppleFAX Modem ROM Upgrade

Revised: 4/26/89
Security: Everyone

AppleFAX Modem ROM Upgrade

=====

This article last reviewed: 1 December 1988

Apple has revised the ROM on the AppleFAX Modem main logic board to correct two problems. First, the AppleFAX modem timeout (error -401) when sending a FAX to Pitney Bowes facsimile machine models 8210 and 9200. Second, the AppleFAX modem, when connected to certain phone environments, does not answer a ringing line. Effective immediately, Finished Goods and Service is shipping AppleFAX Modem main logic boards with the upgraded Revision 1.1 ROM. You can identify a card with the new ROM by looking at the revision letter (B) following the part number on the board.

UPGRADE PROGRAM

An upgrade program is available for one year to customers whose AppleFax Modems have serial numbers with the first four characters below F833. The serial number is located on the bottom of the AppleFax Modem.

Upgrade Reimbursement

To obtain Labor, Parts Credit, and Parts Margin reimbursement for the ROM upgrade, return the old ROM to Apple and record the ROM part number on the SRO form. In addition, record the repair extension authorization code 8G0001 in the Warranty Information section of the SRO.

All main logic boards returned to Apple for repair are automatically being upgraded with the new-revision ROM. When you receive a repaired AppleFAX Modem main logic board from Apple, you can be assured it has the latest revision ROM.

To upgrade your existing AppleFax Modem main logic board Service Stock inventory, order the replacement ROM through the Advanced Exchange Program and return the old ROM to Apple.

Macintosh II Internal Disk Drive Appears Write Protected

Revised: 7/17/92
Security: Everyone

Macintosh II Internal Disk Drive Appears Write Protected

=====

Article Created: 26 April 1989
Article Last Reviewed: 17 July 1992
Article Last Updated:

Problem: The Macintosh II internal floppy drive appears to be write protected. If the drive is replaced and the top cover reinstalled, the same symptom reappears.

Cure: Test the system without the top cover installed. If the drive tests properly, check the the grounding tabs on the RFI shield near the drive. One of them may be bent inward, which pushes the write-protect switch on the mechanical assembly downward, causing the failure. Bend the tab back to its proper position and reinstall the top cover. Test the system to make sure the drive is functional.

Apple IIGS: Resetting The Control Panel And Logic Board Problems

=====

Article Created: 1 May 1989

Article Change History

10/27/92 - REVISED

- To clarify the differences between the ROM 01 and ROM 03 CPUs.

TOPIC -----

Some Apple IIGS problems can appear to be caused by a faulty, main logic board. For example, if a user was to set both the foreground and text colours to black, no video would be apparant. Here's how to reset the video standards to verify the problem lies in software:

DISCUSSION -----

For a ROM 01 GS:

Power down for 10 seconds. Power up and hold control-open apple-esc for a few seconds and a menu with three choices will appear on the screen. Press the down arrow key once, then return (accesses the control panel). Next, press the down arrow key again and hit return (selects the "Display" control panel). Finally, hit the up arrow key and press the right arrow. This will reset the display standards.

For a ROM 03 GS:

Power down for 10 seconds. Power up and hold control-open apple-esc for a few seconds, and a menu with three choices will appear on the screen. Press the Return key (accesses the control panel). Next, press the down arrow key and hit return (selects the "Display" control panel). Finally, hit the up arrow key and press the right arrow. This resets a ROM 03 GS' display standards.

If, after resetting the Control Panel as indicated, the symptoms still

occur, contact your Apple reseller who can refer to the Apple IIGS Technical Procedures for further troubleshooting information.

AppleCAT: Macintosh IIX, Macintosh IICx, and Macintosh SE/30

Revised: 4/26/89
Security: Everyone

AppleCAT: Macintosh IIX, Macintosh IICx, and Macintosh SE/30

=====

This article last reviewed: 3 April 1989

NOTE: This article applies to SOME of but not ALL Macintosh 68030 systems.

On some 68030 systems, AppleCAT II/IIX version 2.3, AppleCAT IICx version 1.0, and AppleCAT SE/30 version 1.0 are indicating failure of all four DRAM SIMMs in bank B despite there being NO DRAM installed in bank B. This problem can occur on all Macintosh IICx units, and on Macintosh IIX or Macintosh SE/30 units that contain certain ROM (not DRAM) SIMMs. The ROM SIMM in question has the part number 630-4339 printed on the board itself.

If the AppleCAT diagnostic is used to test units with these ROM SIMMs, it will first indicate that all bank B DRAM should be replaced. If the diagnostic is continued, it will indicate that the logic board should be replaced. However, the logic board should NOT be replaced; the diagnostic has incorrectly assumed that bank B contains DRAM.

Proper operation of the Macintosh IIX, IICx and SE/30 can still be tested by using the appropriate MacTest diagnostic. It can also be tested by installing DRAM in bank B before using AppleCAT.

For complete information please contact your regional Technical Support center.

LaserWriter: Printer Ready But No Paper Pickup

Revised: 4/26/89
Security: Everyone

LaserWriter: Printer Ready But No Paper Pickup

=====

This article last reviewed: 7 April 1989

Problem: A LaserWriter powers on normally, the fuser comes on, main motor rotation occurs, and the green LED begins blinking. As soon as the printer is ready to generate a test print, the main motor turns on for approximately two seconds, all of the LEDs turn off, and no paper is picked up from the tray.

Cure: Replace the main motor and/or inspect the two pink wires going from the main motor to the DC Controller. These wires can be easily damaged or pinched against the chassis when the DC Power Supply and Main Motor Drive PCB is mounted. If no damage is found, then disconnect connector J503 and check for a resistance of approximately 265. If the resistance varies a great deal, then motor replacement will be necessary.

LaserWriter Plus: No Print or Print Takes Long Period of Time

Revised: 5/2/89
Security: Everyone

LaserWriter Plus: No Print or Print Takes Long Period of Time

=====

This article last reviewed: 24 April 1989

Problem: LaserWriter Plus takes a long time to print out or does not print at all.

BEFORE YOU START: Familiarize yourself with the LaserWriter Technical Procedures. Be sure to follow proper ESD procedures.

Cure: Check to see if the upper half rear latch is broken. If it is, replace the upper half rear latch.

Discussion: If the upper unit rear latch is broken off, the gears do not mesh correctly, causing the LaserWriter Plus not to print.

If the problem still occurs, refer to the LaserWriter Technical Procedures troubleshooting section for more information.

Macintosh SE: Miscellaneous Problem/Cures

Revised: 5/2/89
Security: Everyone

Macintosh SE: Miscellaneous Problem/Cures

=====

This article last reviewed: 24 April 1989

BEFORE YOU START: Familiarize yourself with the Macintosh SE Technical Procedures. Be sure to follow proper ESD procedures.

Problem #1: Macintosh SE resets itself and gives ID=10 error. Also video and sound are distorted.

Cure #1: The Macintosh SE contained a 3rd party add-on card in the expansion slot. The card was removed and the Macintosh SE passed Macintosh SE diagnostics. The expansion slot on the Macintosh SE logic board was not working properly. Replace Macintosh SE main logic board and retest the system.

Problem #2: The Macintosh SE reboots by itself, this happens even when no applications are running and only the Finder is active. The rebooting occurs intermittently.

Cure #2: The Hard Disk may contain an old version of system software (4.0 or older). There may also be soft errors found when the hard drive is tested using HD Diagnostics. Remove system and finder from the drive. Back up the data of the hard drive. Then use HD diagnostics destructive test to destroy the formatting of the HDA and remove all of the soft errors. Reinitialize the HDA using the HD Setup program, install system software, and restore the data.

If the problems still occur, refer to the Macintosh SE Technical Procedures for more troubleshooting information.

AppleShare and Bad Master Directory Block Message

Revised: 5/4/89
Security: Everyone

AppleShare and "Bad Master Directory Block" Message

=====

This article last reviewed: 14 February 1989

If you are working on a server, and find that when you "trash" (dismount) the INTERNAL volume, you get a message that says "Volume is trashed Master Directory Block Bad". Although there may be no other immediate ill effect, ignoring a message of this nature is not a good idea. BACK UP the volume in question before proceeding.

After you have made a backup, shut the server down and run AppleShare Admin. The purpose here is to use AppleShare Admin to verify the volume. It is likely that it will also report some form of error. Also, try testing the drive at a lower level using HD SC Setup. If the drive passes the test, and you have run AppleShare Admin, try bringing the server back up.

If the message continues to appear, try some disk utilities on the drive -- beginning with Disk First Aid as another test, and then on to a package such as Symantec Utilities. If none of this works, we would suggest reformatting the drive and restoring it from the backup.

Although this is potentially a lot of work, the integrity of master directory blocks is critical and well worth the effort -- if only for peace of mind.

AppleTalk Bridges: RTMP Broadcasts

Revised: 5/4/89
Security: Everyone

AppleTalk Bridges: RTMP Broadcasts

=====

This article last reviewed: 14 February 1989

AppleTalk protocol, under certain conditions, sends packets out onto the Ethernet network in which the Ethernet source address contains all 1s (Fs).

The packets with the "all Fs" as addresses are broadcast packets that are sent out periodically by AppleTalk bridges. The Routing Table Maintenance Protocol (RTMP) is used by AppleTalk bridges to maintain their routing information to enable them to send packets to the appropriate bridges and networks connected to those bridges.

It is part of the RTMP specification that, every 10 seconds, each AppleTalk bridge sends a broadcast RTMP packet in order to keep the routing information for the network current.

AppleShare PC 1.1: New Features

=====

This article last reviewed: 17 March 1989

The primary fix delivered in version 1.1 of AppleShare PC concerns interrupt handling:

- In version 1.0, network devices had a tendency to randomly "disappear" from the network. The resolution of this issue was the main reason for creating version 1.1.

The other change to version 1.1 concerns international character sets:

- This change provides a method of mapping the MS-DOS international characters to the Macintosh OS international characters.

(NOTE: The current software, AppleShare PC 1.2, includes these improvements.)

AppleShare PC: "Intermittent Connection Anomaly" Eliminated

=====

This article last reviewed: 17 March 1989

AppleShare PC version 1.0 displayed an "intermittent connection anomaly". That is, it occasionally dropped connection to the printer, was randomly unable to see the printer or the servers, and so on.

The primary change in later versions concerned this intermittent network connection. The first step in resolving the connection issue is to update all AppleShare PC workstations to the current software (currently, v1.2 is the latest). There is no point considering other possible causes of disappearing network resources until the PC workstations are updated.

LocalTalk PC Troubleshooting

Revised: 11/16/93
Security: Everyone

LocalTalk PC Troubleshooting

=====

Article Created: 14 March 1989
Article Reviewed/Updated: 16 November 1993

TOPIC -----

This article describes troubleshooting for the Apple LocalTalk PC card and AppleShare PC software.

DISCUSSION -----

The LocalTalk PC Card and the AppleShare PC software were sold to Farallon and are marketed under the name PhoneNet PC. Please refer to Farallon for support on the PhoneNet PC product line.

In its most basic configuration, the PC LocalTalk Card can only print to a LaserWriter over an AppleTalk network with the software included with the card.

To make the PC become a client on AppleShare, print to a LaserWriter as a native MS-DOS-type printer (directly address LPT1: / LPT2: and so on), and have access to other AppleTalk services, you must have AppleShare PC software on the PC, too.

When printing to the LaserWriter just from the utility software that comes with the card, and not from AppleShare PC, the file to be printed must be stored to a disk first (either floppy or hard disk). Most of the more powerful MS-DOS word processors provide PostScript output, but -- because of the limitations of the software provided with the LocalTalk PC Card -- not directly to the LaserWriter.

Again, the PostScript information generated by the word-processing program must be stored on disk as an intermediate step. Before the PostScript file can be sent to the printer, a PostScript initialization file must be sent to the printer first. It is possible that each PC application that outputs PostScript may need a different initialization file.

The PostScript initialization file that comes with Microsoft Word 4.0 is called POSTSCR.P. The tool that you send the file to the printer with is called LWPRINT.EXE and comes with the basic PC LocalTalk option card. As per the instructions in the LocalTalk PC card manual (pages 74, 75), to send the PostScript initialization file to the LaserWriter, type in the following at the DOS prompt: LWPRINT -A POSTSCR.P and press <Enter>.

At this time, if all is well, you will be returned to the DOS prompt with no error messages. You can then call up the LaserWriter.EXE program and follow the instructions in the PC LocalTalk manual to print out your PostScript output. The initialization file needs to be sent to the printer only when the printer is first being used by the PC, if the printer has been reinitialized by another machine (like a Macintosh), or if the power to the printer has been interrupted.

However, due to operational environments of MS-DOS, you may run into problems. For example, if all PC LocalTalk utilities are in one subdirectory on the user's hard disk and that subdirectory is in the PATH command's search path, you can access LWPRINT and LaserWriter from anywhere in the DOS directory structure.

If the <file name> specified as an argument for the LocalTalk Utilities -- that is, - LWPRINT -A <filename> -- is not in the current directory, you will get a message saying "CAN'T OPEN PRINT FILE <filename>". If this happens, no printer initialization will take place and any subsequent tries to send PostScript files to the printer via the LaserWriter.EXE program will result in printer error messages. Just make sure that the files concerned (utility programs, printer initialization files, and data files) are really where you specify them to be.

LocalTalk PC Card: Compatibility of Third-party Devices

Revised: 5/4/89
Security: Everyone

LocalTalk PC Card: Compatibility of Third-party Devices

=====

This article last reviewed: 23 March 1989

There is no firm rule as to which third-party devices will work with the LocalTalk PC card.

Apple tests the LocalTalk PC card in a variety of MS-DOS machines, from the original IBM PC through the newest compatibles based on the 286 or 386, clocked at 16 MHz, 20 MHz and 25 MHz.

One element that is known to cause incompatibility is a card bus running at 8 MHz. Machines with bus speeds of 8 MHz have caused difficulties for many cards, Apple's LocalTalk PC card among them.

If a problem occurs for a different reason -- that is, the machine has a standard bus speed -- it involves other areas of the network, and becomes a more complicated problem to solve, requiring a detailed examination of the equipment used and the anomalies being experienced.

ADSP Development Kit Available From APDA

=====

This article last reviewed: 6 April 1989

ADSP is the AppleTalk Data Stream Protocol. The ADSP Development Kit, v1.0, is now available from APDA. It is for programmers who

- want to open, read from, write to, or close ADSP data streams, or
- need to know about ADSPOpen, ADSPRead, ADSPWrite, and ADSPClose calls available to Macintosh programmers

This product is described in the Winter 1989 APDAllog on page C-44. It was also listed in the previous APDAllog, but was difficult to find and was not necessarily available then.

For more information, search under: "APDA"

AppleTalk and EtherTalk Packets: How They Work Together

Revised: 5/4/89
Security: Everyone

AppleTalk and EtherTalk Packets: How They Work Together

=====

This article last reviewed: 23 March 1989

The AppleTalk packet is encapsulated within an Ethernet packet. The Ethernet packet contains the Ethernet address of the receiving device, so only that device will accept and inspect the packet. Any AppleTalk device connected directly to an Ethernet uses Address Resolution Protocol (ARP) to determine the Ethernet address of the AppleTalk device it wants to send a packet to.

This means that all address resolution and Ethernet packet addressing occur within the sending AppleTalk node. For example, a Macintosh II, using an EtherTalk card and the EtherTalk drivers and sending to another Macintosh II on the same Ethernet, inspects its ARP address tables and sends an AppleTalk packet encapsulated within an Ethernet packet addressed specifically for the receiving Macintosh II. The receiving Macintosh II strips the Ethernet information from the packet and processes the AppleTalk packet. No other Ethernet device does anything with that packet, unless it is a device like a protocol analyzer peeking at packets.

In the case of an AppleTalk device on a LocalTalk on the other side of a bridge (like a Kinetics FastPath), the Ethernet packet is addressed to the FastPath. The FastPath takes the packet, strips off the Ethernet information, and sends the packet out onto the LocalTalk network.

AppleTalk over T1 Lines

Revised: 7/23/93
Security: Everyone

AppleTalk over T1 Lines

Article Created: 4 May 1989
Article Reviewed/Updated: 22 July 1993

Some users have a Hayes InterBridge connected to AT&T System 75 PBXs to communicate to other, out-of-state sites' LocalTalk networks. The configuration:

LocalTalk to Hayes InterBridge -> AT&T over T1 to AT&T <- Hayes InterBridge to LocalTalk

This solution has worked reliably, but these users are interested in speeds greater than 19,200 baud. They want to know if they can get full LocalTalk 230.4K baud speed over their T1 connection, and what equipment will allow the higher bandwidth.

Ethernet is possible, of course, but might be too expensive.

Another possible solution -- not inexpensive, but perhaps less costly than switching over entirely to Ethernet -- is Network Systems' (formerly VitaLink Communications Corporation) products for T1 lines. A useful configuration might be:

LocalTalk <-> FastPath <-> VitaLink box <-T1-> VitaLink box <-> FastPath <-> LocalTalk

This uses Ethernet as the transport medium through the T1 connection, but the basic network remains LocalTalk.

There is more than one solution available, giving speed ranges from 64 kbps up to the full speed of the T1 circuit. The two determining factors are the cost of the hardware (faster being more expensive), and what else the T1 circuit is being used for. It is possible to use the entire bandwidth of the T1 circuit for the network connection.

In the configuration above, the T1 circuit resembles an Ethernet backbone to the LocalTalk-based networks. The FastPaths are necessary to bridge the

..TIL03639-AppleTalk_over_T1_Lines.pdf

Ethernet provided by the VitaLinks to the LocalTalk networks.

To locate a vendor's address and phone numbers, use the vendor name as a search string..

Apple SuperDrive and Double-Density Disks

Revised: 8/22/91
Security: Everyone

Apple SuperDrive and Double-Density Disks

=====

Article Created: 4 May 1989
Article Last Reviewed: 22 August 1991
Article Last Updated: 22 August 1991

TOPIC -----

This article discusses the disks required by the Apple SuperDrive (formerly Apple FDHD).

DISCUSSION -----

In the DOS environment, you can format a 720K double-density disk so that it will appear to be a high-density 1.44MB disk.

However, you must use a genuine high-density disk to translate data from MS-DOS to Macintosh OS using the Apple SuperDrive Apple File Exchange.

The SuperDrive looks for the additional "bonus hole" in the upper left-hand corner of the disk. If the hole is not there, the drive will not recognize the MS-DOS disk as a high-density disk.

A high-density disk can be recognized by the additional hole as well as the letters HD on the disk.

High-Density and Double-Density Formats Not Interchangeable

=====

Article Created: 4 May 1989
Article Last Reviewed: 22 August 1991
Article Last Updated: 22 August 1991

TOPIC -----

This article discusses the protection feature of the Apple SuperDrive (formerly Apple FDHD) that restricts the media type to high-density disks.

DISCUSSION -----

When using Apple File Exchange (AFE) and the SuperDrive, AFE does not recognize high-density disks formatted as 720K disks in the SuperDrive.

The SuperDrive does NOT recognize a disk as a high-density (1.44MB.) disk unless the disk has the "bonus" hole, which all high-density disks have. This is a hardware feature of the drive--not a limitation.

High-density media are physically different from the standard double-density media, and they are not compatible with each other. The hole prevents the incorrect use of high-density or double-density disks with the SuperDrive.

IBM systems and most compatibles will allow you to format a double-density disk as a high-density disk and vice versa. This is not the case here. There is no way to bypass this protection feature.

HyperCard Serial Port Toolkit: Port B Data Loss Problem

Revised: 7/23/92
Security: Everyone

HyperCard Serial Port Toolkit: Port "B" Data Loss Problem

=====

Article Created: 9 May 1989
Article Last reviewed: 15 February 1989
Article Last Updated: 22 June 1992

If you are using the HyperCard Serial Port Toolkit to read data coming into your Macintosh on both serial ports, you may experience problems with Port B (the printer port) losing data. For example, this can happen when inserting a floppy disk.

This problem is not due to either the serial driver or the interrupt priority. The suggested limitation to the printer port of 300 baud communications or less and output-only connections is caused by the Disk Driver. The Disk Driver, which must turn off interrupts during disk accesses, will buffer the modem port only: it does NOT buffer the printer port.

While you can tell the sender to stop sending before writing to a floppy disk, there is no safe and supported way to get around a disk insertion. You should not be using the two ports in this way, since communications of both ports cannot be guaranteed. If the program is to work on a Macintosh II, CommCard from SuperMac Technologies will allow additional serial ports on NuBus which will be free of the system interrupts.

If the stack is to run on a Macintosh Plus or Macintosh SE, use a NetSerial from Shiva or a C-Server from Solana Electronics. HyperCard will continue to think it is talking to the printer port as a serial device. The NetSerial or C-Server software will convert the serial information into AppleTalk packets, which will be converted by the C-Server or NetSerial back into serial communications. These devices contain buffers that will resend any AppleTalk packets lost when interrupts are turned off by the receiving Macintosh, as in the case of an inserted disk. This is the same as occurs during any AppleTalk transaction from the printer port.

Editor's Note 22 June 1992: Solana has discontinued business to our knowledge, so we are unable to refer you to them directly for further information.

For more information, search under: "SuperMac", and "Shiva".

HyperCard: Requires XCMD To Dial An All-Digital Phone

Revised: 6/24/90
Security: Everyone

HyperCard: Requires XCMD To Dial An All-Digital Phone

=====

This article last reviewed: 23 February 1989

There is no current way for HyperCard to dial a voice call over an all-digital system, such as IBX, without the use of XCMDs.

The problem is that an IBX is a digital phone switch: it communicates with the handsets digitally, instead of using an analog method such as tones. HyperCard (or any program) cannot use these lines to generate a voice call, because the handsets communicate with the switch using a proprietary (and undocumented) protocol specific to that switch. The only way to originate a voice call from HyperCard is to use a hardware interface that understands analog communications specific to the switch.

If you want to generate a data call, one instrument that can be used on IBX is an ADI (Asynchronous Data Interface), and there are similar instruments available for other switches. The ADI communicates with the Macintosh using ASCII, much as a modem communicates. HyperCard, using XCMDs to perform the serial I/O, can originate a data call and communicate with the answering end. A package of serial XCMDs is available through APDA.

For more information, search under: "APDA".

HyperCard: A Front End to an HP3000

Revised: 9/10/92
Security: Everyone

HyperCard: A Front End to an HP3000

=====

Article Created: 2 March 1989
Article Last Reviewed: 4 June 1992
Article Last Updated:

TOPIC -----

What methods are available to communicate with an HP3000 through HyperCard?

DISCUSSION -----

HyperCard can act as a front end to an HP3000 using either of two possible solutions currently available. One is a lower-level solution requiring more work, while the other does much of the work for you.

The lower-level solution is the set of serial XCMDs for HyperCard available from the Apple Programmers and Developers Association (APDA). These implement serial communication at a level that allows you to design the front end any way you want. Choosing this requires that you deal with all of the communication, terminal emulation, and formatting information sent from the HP3000.

The second option is a set of external commands and code resources called "FITOS" from MITEM Corporation. These include a number of different terminal emulators, including at least one HP terminal type. The advantage of this package is that it handles everything except the actual information that would normally be presented to the user. You don't have to worry about the communications protocols used or the terminal formatting characters sent by the host. One possible disadvantage is that if it does not support the type of terminal that you need them to support, you would have to deal with the terminal emulation yourself.

For more information, search under: "MITEM" and "APDA".

HyperCard: Global Variables Change at New Application Launch

Revised: 6/24/90
Security: Everyone

HyperCard: Global Variables Change at New Application Launch

=====

This article last reviewed: 6 April 1989

If you launch an application after creating a global variable in HyperCard, when you return to HyperCard from the application, the global variable is no longer defined. You will be running under the Finder.

If you want the value of a HyperCard global variable to be saved across a launch, you will need to use the "suspend" and "resume" messages, save the value of the variable somewhere, and then restore it.

(NOTE: If you are running HyperCard under MultiFinder, you will not have this problem since HyperCard stays active when you open another application.)

HyperCard: Memory Requirements

=====

Article Created: 6 April 1989
Article Last Reviewed: 10 July 1992
Article Last Updated: 10 July 1992

HyperCard is designed to run on a 1 MB Macintosh system (2 MB under System 7), but this does not ensure that you will have access to all of the tools all of the time. For example, it is possible to create a card on a 2 MB machine that cannot even be opened on a 1 MB machine. Also, HyperCard keeps track of new stacks and/or cards as they are opened. In time, this could use up enough memory to prevent the use of the painting tools. Setting the memory requirements down to 800K will make the problem worse, not better, if MultiFinder or System 7 is running; it will do nothing if running only the Finder under System 6.

Using the "Minimum System" and restricting INITs will reduce the total memory used by the system and may also prevent, or slow down, the above problem. It is hard to make recommendations, because there are many possible variations as to the contents or complexity of the stacks being used.

Some suggestions: - Load a single stack and don't switch to other stacks unnecessarily - Compact stacks on a regular basis - Don't use complex graphics on a 1 MB system unless absolutely necessary.

It may also be necessary to quit to the Finder on a regular basis and then relaunch HyperCard, as this will free the memory used by HyperCard to track the cards opened during the session.

HyperCard 1.2.1: Problem Controlling Cursor Shape

=====

Article Created: 21 February 1989
Article Last Reviewed: 14 July 1992
Article Last Updated:

Some users have reported what seems to be a problem with HyperCard: that you lose the cursor shape you have set.

The problem may be that you are setting the cursor within a script and expecting it to stay set until you change the setting at a later time.

The HyperCard system sets the cursor to the current tool at "idle". An idle state is one in which no events have occurred, and you are not operating inside a handler. For example, when you choose the browse tool, the cursor is a hand, except when it is over unlocked fields, where it appears as an insertion bar.

It may be that once you exit all scripts, Hypercard resets the cursor to the hand.

If you wish to globally change the HyperCard "hand" cursor, such specific editing functions as "set cursor" will not do the job, since "set cursor" works only inside its called handler, creating the above situation.

Instead, using ResEdit, open the "FONT" and the "BAD FONT" resources. Find the character with ASCII value 152. Modify this to change the hand cursor in HyperCard.

A/UX: Support for Programs Written Under MacAPP

Revised: 9/16/92
Security: Everyone

A/UX: Support for Programs Written Under MacAPP

=====

Article Created: 14 February 1988

Article Change History

08/27/92 - REVIEWED
o For technical accuracy.

TOPIC -----

Programs written under MacAPP in the Macintosh OS can run under A/UX, if they follow the guidelines for A/UX and Macintosh programming specified by

Developer Technical Support's Tech Notes and
"Inside Macintosh", Volumes I through V
(available from Addison-Wesley).

DISCUSSION -----

These applications will not have access to UNIX services or be able to communicate directly with UNIX processes. This is because there are no libraries for the UNIX calls available under the Macintosh OS in MPW or any other development system that we are aware of.

Under A/UX, libraries do exist, as do the necessary Macintosh libraries for writing Macintosh-style programs that perform UNIX functions and system calls. However, there is no support for object-oriented programming similar to MacAPP. The C compiler available with the system is a standard C compiler without any object-oriented extensions.

A/UX: File Transfer to and from VAX (9/94)

Revised: 9/7/94
Security: Everyone

A/UX: File Transfer to and from VAX (9/94)

Article Created: 9 May 1989
Article Last Reviewed: 6 September 1994

TOPIC -----

File Transfer to and from a DEC VAX.

DISCUSSION -----

There are several ways to transfer files between A/UX and a VAX, depending on how the communication line is connected physically--that is, whether it is connected via modem (telephone line), direct hard-wired, or on an Ethernet network.

In A/UX, there are two serial TTY ports (modem and printer). You can use either one or both of these two ports to connect to the other end of a VAX machine.

(NOTE: The A/UX distribution is configured with tty0 or dial-in modem port [getty enabled] and tty1 for printer port [getty disabled]. In A/UX 3.0 both ports are disabled by default)

- If the VAX machine is running any flavor of UNIX systems, such as Berkeley 4.2 or 4.3 or AT&T System V, and the serial line connections (modem or hard-wired) are used, you can use the 'cu' or 'tip' commands in A/UX for terminal connection and file transfer interactively. You can use the 'uucp' (UNIX-to-UNIX copy) command for automatic batch file transfer.
- If the VAX machine is running DEC VMS, one possible solution is to use public domain Kermit software on both A/UX and VMS for connection and file transfer.
- If the A/UX and VAX UNIX are connected via Ethernet, then 'telnet', 'rlogin', 'ftp', and 'rcp' commands in A/UX can be used for terminal connection and file transfer. If the VAX supports NFS (Network File System), then file transfer becomes transparent as long as the remote file system is mounted.

AppleCD SC Audio: Entering Song and Disk Titles

Revised: 5/9/89
Security: Everyone

AppleCD SC Audio: Entering Song and Disk Titles

=====

This article last reviewed: 21 February 1989

Some of you have experienced a problem with AppleCD SC using the v2.0.1 Installer Disk:

You enter the CD Name and Tracks and then save them (this loads the data into CD Remote Programs file). Then, when you insert the CD back again, the Track names do not show up (as they did with Installer v1.0). Also, Audio CD is named Audio 1, Audio 2, etc., each time the same CD is removed and inserted.

The song and disk titles are saved in the "CD Remote Programs" file in the System Folder. The entry in the CD Remote Programs file is cross-referenced against total time of audio, number of tracks, length of tracks, and various other unique characteristics of individual audio CDs. There are three resources in the "Programs" file: "IndX", "Program", and "STR#":

- "IndX" is the cross reference between the CD and the file.
- "Program" contains the sequence, if programmed, for playback of the tracks.
- "STR#" contains the song and disk titles.

This cross-reference scheme lets you type variations of the disk and song titles. The CD ID (IndX) is used to access the correct titles (STR#) and programmed sequence (Program).

The naming of the desktop's audio CD icon is based on an evaluation of total time, individual track lengths, and various other unique aspects of an individual audio CD. If you eject an audio CD (as opposed to dragging it to the trash), the system software may recognize an audio CD that played earlier. Otherwise, a counter is incremented and the name becomes "Audio _" (the "_" portion of the name being the incremented number). Thus, the sequence of Audio 1, Audio 2, Audio 3, and so on is to be expected.

HyperCard: Laser Video Control? (12/95)

Article Created: 9 May 1989
Article Reviewed/Updated: 22 December 1995

TOPIC -----

This article describes Laser Video Disc players and availability of XCMDs for controlling LaserDisc Players from HyperCard.

DISCUSSION -----

Most laser video is provided on 12-inch LaserDiscs. Many of the industrial-grade LaserDisc players provide serial connections. Control of the 12-inch LaserDisc players is provided via XCMDs for HyperCard. We are unaware of any industrial-grade LaserDisc player that supports the 5-inch CD-V format.

Depending on the source, CD-V may mean only the 5-inch format, or CD-V may mean 5-inch, 8-inch, and 12-inch formats. To support all three video formats, use Voyager Company's The Box to control a Pioneer 1030 or Pioneer 3030. The 1030 and 3030, which are called "combination players", support CD audio, 5-inch CD-V, 8-inch LaserDisc/CD-V, and 12-inch LaserDisc/CD-V. The Box comes with HyperCard XCMDs for controlling these two disc players, among others.

Of the disc players on the Voyager list that we have, the Pioneer 1030 and 3030 are the only LaserDisc players that support multiple disc sizes. Voyager has been adding to the list of supported disc players. Check with them to see if a particular combination player is currently supported.

The Tech Info Library article titled "Locating Vendor Information" can help you search for a Voyager's address and phone number.

Apple Dot Matrix Printer: How to Connect to a Macintosh SE

Revised: 5/9/89
Security: Everyone

Apple Dot Matrix Printer: How to Connect to a Macintosh SE

=====

This article last reviewed: 21 February 1989

You can connect an Apple Dot Matrix printer to a Macintosh SE with a parallel-to-serial/serial-to-parallel converter.

Orange Micro makes a cable specifically for connecting parallel devices into serial ports, whether those ports are on an Apple IIGS, Apple IIc, or a Macintosh. It's called "Grappler C/MAC/GS", and it has a converter built into the cable; it emulates an ImageWriter II and only requires using the ImageWriter driver from a Macintosh.

Problems should be minimal in this connection as long as ImageWriter II-specific features are avoided. Using an early version of the ImageWriter driver (2.3 or before) may even be a workaround for that, since those versions of the driver do not have any ImageWriter II-specific functionality.

For more information, search under "Orange Micro".

AppleScanner: Tips For Printing Scanned Images

=====

This article last reviewed: 6 April 1989

If your AppleScanner presents white lines in the printouts of the scanned half-tone images, it is possible that you are not using the most recent version of the LaserWriter Print Driver (5.2), which is included on the AppleScan disk.

White streaks (otherwise known as Moire patterns) appear in printouts of half-tone images when the Faster Bitmap and/or Bitmap Smoothing print options are selected. This is the default in many applications, so these options must be deselected in the Page Setup dialog within each application.

The AppleScan application automatically deselects these options when used with LaserWriter driver 5.2.

In general, the way to get the best quality of laser-printed halftones from any application is to follow these tips:

- Use the latest print drivers.
- Turn off Faster Bitmap and Bitmap Smoothing print options.
- Turn off background printing in MultiFinder.
- Do not resize a half-tone image within the application. Instead, use the scaling feature within the AppleScan application.

If the application imports TIFF files, you may want try saving the image in that format within AppleScan.

LaserWriter II: Advantages of Using Downloaded Fonts

=====

This article last reviewed: 30 March 1989

The best method for printing from a LaserWriter is by using either fonts downloaded into RAM from a hard disk attached to the printer, or using fonts downloaded into RAM over the network. Both of these methods are better than printing directly from fonts stored on a hard disk.

Here are two more advantages to this method:

- The hard disk attached to the printer can hold hundreds of fonts, compared to the limited font-storage capability of the printer's RAM.
- All users have access to all fonts stored on the printer, freeing valuable disk space at each computer. Users need only to have the screen fonts installed, not the downloadable printer fonts.

This article last reviewed: 23 March 1989

Q: How secure is AppleShare from viruses? Users recognize the threat to folders where others have write access and the ability to affect others using applications contained in those folders, but what about the Server Folder itself? Is the running of VACCINE on an AppleShare server indicated? Is there something better? Is it possible to issue low-level I/O calls (PBWrite and lower?) to server volumes (bypassing any AppleShare built-in security) from other Macintosh systems on the network?

A: The AppleShare server folder itself is quite secure when the server is running. Is it not accessible by any system call, whether high-level or low-level. A virus would only be able to attack folders and files that it has access to. It is not necessary or recommended to install Vaccine in the Server folder on the AppleShare server. If the server is running at the Finder level, it is just as susceptible to viruses as any system.

Viruses: Safety of Boot Blocks (4/94)

Revised: 4/1/94
Security: Everyone

Viruses: Safety of Boot Blocks (4/94)

=====
Article Created: 9 May 1989
Article Reviewed/Updated: 1 April 1994

TOPIC -----

Are a floppy disk's boot blocks potentially vulnerable? If a user is operating a lab where diskettes are handed out and returned, should those diskettes be reinitialized, or will a volume copy suffice? What about hard disks?

DISCUSSION -----

It is highly unlikely that a virus would be able to use the boot blocks as a mechanism for spreading itself on either a floppy disk or hard disk.

However, a virus can change the information contained in the boot blocks and thereby cause problems. For floppy disks, a volume copy, using an application such as Apple's DiskCopy, from a "known good, virus-free" original replaces all sectors on the disk and eliminates the possibility of virus being on that disk.

Further, for either floppy disks or hard disks, any Macintosh virus detection application can scan and remove known viruses.

Article Change History:
1 April 1994 - Added references to Disk Copy, hard disks and virus detection software references.

CODE Resource ID=0: Jump Table Implementation

Revised: 5/9/89
Security: Everyone

CODE Resource ID=0: Jump Table Implementation

=====

This article last reviewed: 30 March 1989

CODE resource ID=0 in an application is used to implement a jump table for routines that are called from one code segment but reside in another code segment of the application. The first 8 bytes of CODE 0 include such information as the jump table length, the offset from register A5, and so on.

Beginning at the ninth word (usually referred to as "word 8", because numbering starts at 0) are the actual jump table entries for each of the routines that are called from outside their segments. Each entry is four words long. The first word is the offset in hex of the routine being called. This offset is from the beginning of the segment to which the routine belongs.

The next three words are the instructions that will be executed; they have the format:

```
MOVE.W    #$0001,-(A7)
_LoadSeg
```

The #\$0001 word identifies the segment that is to be loaded and contains the routine. In the example above, code segment 1 contains the routine. In hex, a sample jump table entry is:

```
WORD      1      2      3      4
          298C 3F3C 0001 A9F0
```

- 1) The offset
- 2) MOVE.W
- 3) The code segment
- 4) _LoadSeg

ImageWriter: Printing Superscripts and Subscripts

Revised: 5/17/89
Security: Everyone

ImageWriter: Printing Superscripts and Subscripts

=====

This article last reviewed: 23 March 1989

There are two ways of creating super/subscript printouts on the ImageWriter (this applies only to ImageWriters with a serial number above 216001; those with lower serial numbers do not super/subscripting):

Method #1) The diskette called "ImageWriter Tool Kit (v1.5)" contains a half-high character set designed for super/subscripting use. To use it, download the character set to the printer prior to using Bank Street Writer. (This download function is a function on the tool kit disk.)

Method #2) If full-size characters shifted half a line up or down are satisfactory, then issue the following codes. The codes to do super/subscripting are not stated as such. Super- and subscripting require the printer to shift forward or reverse, print some characters, then shift back. The reference card in the manual is also not clear what the proper code is for this function.

To subscript:

- 1) Print some text.
- 2) Set a new line feed pitch.
- 3) Issue a forward line feed (for subscripting).
- 4) Print the character(s) to be subscripted.
- 5) Set reverse line feeding.
- 6) Issue a line feed.
- 7) Reset to original line feed pitch.
- 8) Continue printing.

To superscript:

- 1) Print some text.
- 2) Set a new line feed pitch.
- 3) Set reverse line feeding.
- 4) Issue a line feed (for superscripting).

- 5) Print the character.
- 6) Set forward line feeding.
- 7) Issue line feed.
- 8) Reset to original line feed pitch.

The ImageWriter's "optional line feed function" suppresses the Carriage Return when issuing a Line Feed. (As you can see, none of this is very simple).

A possible scenario for sending codes to do superscripting from BASIC (running under ProDOS):

```
10 D$=CHR$(4):REM CONTROL D
20 A$=CHR$(27)+CHR$(108)+CHR$(49):REM ENABLE OPTIONAL LINE FEED FUNCTION
   CODE
30 B$=CHR$(27)+CHR$(84)+"10":REM SET LINE PITCH TO LESS THAN HALF LINE
40 C$=CHR$(27)+CHR$(102):REM FORWARD LINE FEED CODE
50 E$=CHR$(27)+CHR$(114):REM REVERSE LINE FEED
55 F$=CHR$(27)+CHR$(84)+"24":REM SET LINE PITCH BACK TO FULL SIZE
60 PRINT D$;"PR#1":REM IF THIS SLOT IS WHERE THE PRINTER CARD IS LOCATED
70 PRINT "This text is normal";:REM NORMAL TEXT
80 PRINT A$;:REM ENABLE OPTIONAL LINE FEED FUNCTION
85 PRINT B$;REM SET LINE PITCH
90 PRINT CHR$(31)+"1";:REM FEED ONE BLANK LINE OF PAPER
95 PRINT CHR$(27)+CHR$(39);:REM SWITCH TO CUSTOM FONT
100 PRINT "THIS TEXT IS SUBSCRIPTED";:REM SUBSCRIPTED TEXT
110 PRINT E$;:REM SET REVERSE LINE FEED
120 PRINT CHR$(31)+"1";:REM FEED ONE BLANK LINE OF PAPER
125 PRINT F$;:REM SET REVERSE LINE FEED
135 PRINT CHR$(27)+CHR$(36);:REM SWITCH BACK TO NORMAL FONT
140 PRINT "This text should be normal again"
145 PRINT C$;REM RESET TO FORWARD LINE FEED
150 PRINT D$;"PR#0"
160 END
```

Here is an example of how to enter the codes into Bank Street Writer:

To Begin Subscripting

Characters:	ESC	1	1	ESC	T	1	2	(CONTROL)_	1
ASCII Codes:	27	108	49	27	84	49	50	31	49

To End Subscripting

Characters:	ESC	r	(CONTROL)_	1	ESC	f	ESC	A	ESC	1	0
ASCII Codes:	27	114	31	49	27	102	27	65	27	108	48

To Begin Superscripting

Characters:	ESC	1	1	ESC	T	1	2	ESC	r	(CONTROL)_	1
ASCII Codes:	27	108	49	27	84	49	50	27	114	31	49

To End Superscripting

Characters:	ESC	f	(CONTROL)_	1	ESC	A	ESC	1	0
ASCII Codes:	27	102	31	49	27	65	27	108	48

(NOTE: The second character in the command sequence that begins sub- or superscripting, and the next-to-last character in the sequences that ends sub- or superscripting, is a lowercase "L".

The last character in the sequences that ends sub- or superscripting is a zero.

HyperCard: Printing a Scrolling Text Field

Revised: 4/11/91
Security: Everyone

HyperCard: Printing a Scrolling Text Field

=====

This article last reviewed: 30 March 1989

Printing the complete text residing in HyperCard scrolling fields can be done by printing a report of the HyperCard stack.

Unfortunately, one drawback to printing a report is that all the cards in the stack with the selected field name will be printed: there is no easy way to select only one card for printing without cutting and pasting.

Another way to print the entire contents of a scrolling field with only selected information and cards would be to use a report utility like Activision's "Reports".

For more information, search under: "Activision".

Apple IIGS System Disk 5.0: Overview

Revised: 10/4/89
Security: Everyone

Apple IIGS System Disk 5.0: Overview

=====

This article last reviewed: 25 September 1989

Apple IIGS System Disk 5.0 is the new release of system software for the Apple IIGS computer. The main features include:

- Support for AppleShare File Server
- Speed, speed, and more speed
- A Control Panel and Control Panel devices (CDEVs)
- Multiple simultaneous installations with the Installer
- 5.25-inch Disk Driver is installed
- Increased ToolBox support

Packaging

The AppleTalk Network User's Guide and AppleShare Apple II Setup Disk are included only in the System Software 5.0 update box. It will not ship with the Apple IIGS hardware system.

The Apple IIGS manual is being rewritten to include the information in the AppleTalk Network User's Guide.

System Requirements

Apple IIGS System Disk 5.0 requires an Apple IIGS with a least 768K of memory when operating on a network. As a stand-alone system the 5.0 System Disk requires only 512K.

AppleShare and Network Support

One of the main new features of Apple IIGS System Software 5.0 is GS/OS support for AppleShare File Server volumes. To use the Apple IIGS with an AppleShare File Server, you need to use version 2.0 or later of the AppleShare File Server

software.

There are a number of additions to GS/OS to support AppleShare. These include:

- Booting GS/OS over the network
- Creation of a 3.5-inch Server Startup Disk
- An AppleShare FST (File System Translator) for GS/OS
- A Control Panel File Server Chooser
- Ability to auto-logon to a server
- Server Logoff
- Finder support of AppleShare

Network Booting

To use the Apple IIGS with an AppleShare File Server, you need to use version 2.0 or later of the AppleShare File Server software. If you have an existing AppleShare File Server you need to order:

Apple IIGS System Software version 5.0

This package includes a new "Apple II Setup Disk". This disk is a Macintosh disk that uses the Macintosh Installer to update the AppleShare File Server 2.0.1 server boot blocks to GS/OS. The boot blocks are sent to the workstation when the user requests network booting from the Apple IIGS. The disk is found in the back of the AppleTalk Network User's Guide that ships inside the stand-alone package. After the Macintosh has been updated, you can use the Apple IIGS Installer (located on the SYSTEM.TOOLS disk) to update the SYSTEM folder on the server hard drive.

All servers on the network should be updated to the new boot blocks at the same time. You should not have boot blocks from Apple IIGS Workstation Software and System Disk 5.0 on the same network. AppleShare File Server will start shipping with the new Apple II Setup Disk mid-summer 1989.

Local Booting

Using a 3.5-inch disk can speed up server boot times. There are two methods of gaining access to an AppleShare File Server from a 3.5-inch disk:

- Local Network Startup
- AppleShare on 3.5-inch Disk

The first method performs the same function as network booting, and the second boots into the Finder.

Local Network Startup saves time and network traffic when booting an entire class of computers at the same time. The Installer update to allow faster network booting is called "Local Network Startup".

The Installer update that lets you boot into the Finder is called "AppleShare on 3.5 Disk". This type of disk is called a "workstation startup disk".

ExpressLoad

ExpressLoad is new with Apple IIGS System Software 5.0 and causes GS/OS to load the system and applications faster. ExpressLoad enhances the standard Apple IIGS System Loader and lets large applications load in a shorter time.

Developers can turn applications into ExpressLoad format using the APW tool called Express or the MPW IIGS tool called ExpressIIGS. A load file must contain resources and code segments in a specific order to be compatible with ExpressLoad. ExpressLoad checks files first to see if they are in the proper format. If the file is not in ExpressLoad format, the application is launched by the normal Apple IIGS system loader.

To save memory, ExpressLoad is loaded only on systems with more than 512K of memory. Before loading ExpressLoad, the system checks to see if there is more than 512K of memory. It will not ExpressLoad into a 512K system.

ToolBox

A number of the toolbox routines have been modified to increase speed. They include "special case" code that causes QuickDraw and other routines to operate faster, based on the parameters that were passed to QuickDraw. Programmers do not have to modify their code to support any of these "special case" routines.

Control Panel and CDEVs

The Apple IIGS System Disk 5.0 includes the Graphics Control Panel, which is similar to the Macintosh Control Panel and Chooser. The Graphics Control Panel is implemented as an NDA (New Desk Accessory). This type of DA is available only to Apple IIGS desktop applications.

The Graphics Control Panel is an expanded facility for controlling any number of system parameters. This functionality lets Apple and third-party developers add Control Panel "devices" (CDEVs). The Graphics Control Panel sets the same information as the existing Apple IIGS Control Panel (now called the Text Control Panel) which is accessed by using the Command-Control-Escape keys. Icons for all CDEVs look the same, letting you identify a CDEV quickly and easily.

CDEVs are located inside the SYSTEM folder, just as fonts and desk accessories:

/disk/SYSTEM/CDEV

Desk Accessories

Like the current Apple IIGS System Disk, Apple IIGS System Software 5.0 supports New Desk Accessories (NDAs). The system can now support 128 NDAs, thanks to scrolling menus. Desk Accessories are in the following folder:

/disk/SYSTEM/DESK.ACCS

SCSI Manager

The SCSI manager has been modified to provide a four-fold speed increase and provide additional SCSI support. The new driver is faster because it is loaded into memory and does not use the firmware on the card. When the driver was written, a number of new features were added:

- Full SCSI Device Support
- 7 Physical Devices
- 32 Volumes per Drive
- Full SCSI Command Support
- Access to Non-ProDOS Partitions
- Support for Magneto-Optic Drives (with a driver)

Apple IIGS System Disk 5.0: ToolBox Changes

=====

This article last reviewed: 05 May 1989

This article summarizes changes and additions to the Apple IIGS ToolBox that result from Apple IIGS System Disk 5.0.

The Toolbox on the Apple IIGS has been modified to support a number of new features that are available to developers. (If these new features are used in a program, the user must have Apple IIGS System Software 5.0 for the software to function correctly.)

The Resource Manager and Text Edit are new for System Disk 5.0.

Additional documentation is available from APDA.

Control Manager

The Control Manager has been modified to provide support for more standard control types, including:

- StatText Control -- Display text messages in a rectangle.
- PictureControl -- Display a picture in a rectangle.
- IconButtonControl -- Icon drawn in a rectangle.
- LineEditControl -- Line Edit item used in List Manager.
- TextEditControl -- Works with new TextEdit Tool.
- PopUpControl -- Provide multiple selection buttons within scrolling lists.
- ListControl -- You can now use the control manager to manipulate items in the List Manager.

Desk Manager

The classic desk accessory (CDA) menu now supports scrolling when more than thirteen CDAs are installed. CDAs are accessed by pressing COMMAND-CONTROL-ESC on the keyboard. Because of this change, selections no longer wrap around the screen. The number of CDAs is limited by disk space and boot time to install

the files. You may have problems if you install more than 128 CDAs.

Event Manager

The Journaling feature is changed, to better support the ReadMouse function.

Font Manager

A problem was fixed in ChooseFont, which caused the system to hang if any update events were pending when the call was made.

Line Edit

Line Edit now supports a password field, in which the characters typed by the user appear on the screen as asterisks (*).

List Manager

The List Manager has been changed to make it easier for programmers to use, and to support new controls in the Control Manager.

Memory Manager

The Memory Manager has been modified to improve system performance.

Menu Manager

The Menu Manager now supports a number of new features, including:

- Outline and Shadow text styles in a menu
- scrolling menus
- pop-up menus

Note Sequencer

The Note Sequencer has been modified to make it easier for developers to create and use sequences in programs.

Print Manager

The PrChoosePrinter call has been removed. Users should use the Control Panel to select printers. If an application makes this call, a dialog appears on the screen telling the user to use the Control Panel to select a printer. When printing in draft mode to a text printer, the driver translates QuickDraw II commands into command sequences for the printer.

QuickDraw II

QuickDraw II has been modified to function faster.

Resource Manager

The Resource Manager is an INIT file that is loaded when the Apple IIGS is started, and stays loaded when the system is running. The Resource Manager maintains the resource fork of a file. This is similar to the resource fork in the Macintosh. This is the first time the a resource fork has existed in the Apple II world. The format of the data is defined by the application. Resources are referred to by a resource type and resource ID number.

Sound Tools

Four new calls have been added to the sound tools, allowing greater flexibility when playing sounds.

Standard File

Standard File has been modified to fully support GS/OS path names. The following are GS/OS values, not the ProDOS FST values. These include:

- 13,107 files in a folder
- 254 characters in a file name (using new calls)
- 508 characters in a path name
- The List Manager is being used
- Scan of AppleShare File Server volume every 8 seconds
- Checks for write-protected volumes and folders
- Displays the lock icon next to current path name
- Calls to support multi-selection calls
- Hook so applications can draw custom list items

Text Edit

This is a new feature of Apple IIGS System Software 5.0. It provides standard text editing for any application. It can be used as a complete text editor or as the core of a simple word processor. It is similar to Text Edit calls on the Macintosh. The following features are included in GS TextEdit:

- Edit any amount of text that fits in memory (not 32K as in the Macintosh)
- Mouse activity for text selection (single, double, triple clicking for text, words, lines)
- Auto word wrap
- Cut, Copy, and Paste
- Some support of control keys for text manipulation
- Stylistic variations in the text (fonts, sizes, style, color).
- Text can contain a "ruler" to format the text
- Four types of justification
- Three kinds of Tab support

- Programmer can limit the amount of information that can be entered
- Vertical scrolling in a window
- Automatic drag selection
- It is FAST

Window Manager

Numerous changes speed things up and support the Resource Manager.

Revised: 4/11/91
Security: Everyone

Apple IIGS System Disk 5.0: Changes to BASIC.SYSTEM

=====

This article last reviewed: 05 May 1989

Two problems were fixed in BASIC.SYSTEM 1.3, and one new feature was added.

MTR Command

The new feature is the MTR command, which lets the user enter the system monitor without having to remember "CALL -151". The user stays in the monitor until issuing Q or Control-C.

Problem Fixes

When two or more Applesoft programs were chained together and the length of the variable table was a multiple of 256, the chain command functioned incorrectly and the program crashed into the monitor or was sent to the ONERR command address. This is fixed in BASIC.SYSTEM 1.3.

BASIC.SYSTEM 1.3 also fixes a problem in BSAVE that caused the old length and load address to be retained when you BSAVED over an existing file.

Apple IIGS System Disk 5.0: Advanced Disk Utility and SCSI Mgr.

Revised: 7/20/95
Security: Everyone

Apple IIGS System Disk 5.0: Advanced Disk Utility and SCSI Mgr.

Article created 05 May 1989

With System Disk 5.0, the Advanced Disk Utility permits a larger number of partitions on a single SCSI drive. The maximum size of each partition is still limited to 32MB. The following table shows the number of possible partitions on a drive, given the drive size.

Drive Size	Max. No. of Partitions
-----	-----
20MB	8
40MB	8
80MB	8
160MB	8
256MB	8
320MB	10
512MB	16
640MB	20
800MB	25
1GB and up	32

SCSI Manager

The SCSI manager has been modified to provide a four-fold speed increase and additional SCSI support. The new driver is faster because it is loaded into memory and does not use the firmware on the card. When the driver was written, a number of new features were added:

- Full SCSI device support
 - 7 physical devices
 - 32 volumes per drive
 - full SCSI command support
- access to non-ProDOS partitions
- support for magneto-optical drives (with a driver)

The firmware must run at normal speed (1MHz) and not at fast speed. The new

drive talks directly to the hardware on the card and may not be compatible with any other existing SCSI interface cards. The SCSI manager was designed to work only with the Apple SCSI interface card.

The SCSI manager can support seven external boxes (a "box" being something that has a SCSI address). Each box can have up to eight devices, and block devices like hard drives can have up to 32 partitions.

The SCSI Manager works by having a device driver for each different type of SCSI device you want to hook up. This allows different types of devices to be added without modifying the external device or the SCSI card. You just need to add the driver to the system. This is how Apple supports SCSI hard disks and the AppleCD SC. The device drivers are located in the following folder:

/disk/SYSTEM/DRIVERS.

Revised: 4/11/91
Security: Everyone

Apple IIGS System Disk 5.0: Disk II/Apple 5.25-inch Driver

=====

This article last reviewed: 05 May 1989

The 5.25-inch Disk driver is now installed on SYSTEM.DISK that ships with GS/OS. You do not need to run the Installer to support the 5.25-inch drive, but you still need to use the Installer to support a SCSI drive.

The 5.25-inch disk driver included with Apple IIGS System Software 5.0 can support up to fourteen 5.25-inch disk drives. The Apple IIGS limits 5.25-inch drives to slots 4, 5, 6, and 7 when the computer is in fast mode. When using the Apple IIGS System Software 5.0 and the 5.25-inch driver, you can now operate 5.25-inch drives in slots 1 through 7, in slow or fast mode.

The 5.25-inch drive does not use a cache, because the 5.25-inch drive does not provide a method of determining a disk switch. The light on the drive flashes when the Finder issues the status call to the 5.25-inch driver. The driver must check the drive to see if a disk is inserted or has changed since the last status call.

Apple II: No Diskless Startup Across Zones

Revised: 5/11/89
Security: Everyone

Apple II: No Diskless Startup Across Zones

=====

This article last reviewed: 23 February 1989

If you are having problems starting a diskless Apple II on LocalTalk over a Kinetics FastPath, from a server residing on Ethernet, it may be because the diskless start-up capability of Apple II workstations is designed to work over a FastPath or other AppleTalk bridges -- but not across zones. If your FastPath has been set up with the Ethernet as a separate zone from the LocalTalk side, this is your problem.

You should also look at the configuration of the FastPath itself. If a Macintosh can access the server normally from the LocalTalk side of the network, then the Apple II should be able to start, because the same network layers are being used for the information transfer. If a Macintosh cannot access the server properly, then you should suspect the configuration of the FastPath itself.

Macintosh System Software: Sharing a Hard Disk

=====

This article last reviewed: 29 February 1989

If you are installing System software on a hard disk that will be shared by different Macintosh models (for instance, both a Macintosh II and a Macintosh Plus), we suggest installing the System software as if the drive is going to be used on a Macintosh II.

A Macintosh Plus ignores the information for a Macintosh II, while providing all the files and resources a Macintosh II will need.

(NOTE: Do not use the minimum Installer scripts for this purpose.)

ProDOS 8: Finding Volume Size using Assembly Language

Revised: 5/10/89
Security: Everyone

ProDOS 8: Finding Volume Size using Assembly Language

=====

This article last reviewed: 8 March 1989

You can determine the number of blocks on a ProDOS-compatible device from assembly language.

On a ProDOS volume, the total number of blocks available is stored on block 2, bytes \$29 and \$2A. The number is in low byte/high byte format: for example, an 800K floppy will have \$40 at byte \$29 and \$06 at byte \$2A.

Byte \$2A contains the first two digits and byte \$29 contains the last two digits. \$0640 is equal to 1600 decimal, which is the total number of blocks on an 800K ProDOS disk.

If you need to determine the number of blocks on a device from the hardware, that information can be obtained regardless of whether or not block 2 is intact.

Check memory locations \$Cs01, \$Cs03, \$Cs05 (s = slot number) for \$20, \$00, and \$03, respectively. If these values are found, then the card in the slot is a disk controller.

Check memory location \$CsFF. If the value is \$00 or \$FF, assume that an Apple Disk II disk controller card is installed (\$00 is 16-sector, \$FF is 13-sector).

Otherwise, check memory location \$Cs07. If the value does not equal \$00, the device is not a SmartPort device, and the total number of blocks for the drive are stored at memory locations \$CsFC and \$CsFD in low-byte/high-byte order.

If the total number of blocks is 0, contact the card manufacturer for details on how to determine the number of blocks.

(NOTE: We do not know of any disk controller that does not store the total number of blocks at memory locations \$CsFC and \$CsFD.)

If the value at memory location \$Cs07 is \$00, the drive is a SmartPort device. To find the number of blocks on the drive, you must make SmartPort status call \$03 (get DIB). This call is documented in the "Apple IIGS Firmware Reference Manual" (Apple # 030-3121-A) on pages 114 through 125, with the most specific information starting on page 121.

HD SC Setup v2.0: How to Set Interleave Factor On a Hard Disk

Revised: 5/11/89
Security: Everyone

HD SC Setup v2.0: How to Set Interleave Factor On a Hard Disk

=====

This article last reviewed: 2 March 1989

With HD SC Setup v2.0, you can a set disk's interleave factor. That is, you can reformat a standard hard disk with a different interleave factor than the one installed.

Make sure the disk you wish to reformat does not contain any valuable data, then follow these steps:

- 1) Run HD SC Setup.
- 2) At the first dialog box, choose the drive you want to initialize.
- 3) Press Command-I.
- 4) This presents a dialog box asking for the interleave factor.
Choose 1 for a 1:1 interleave, 2 for a 2:1 interleave, and so on.
- 5) Now choose Initialize.

Your drive is now reformatted to the specified interleave factor.

MultiFinder: How to Set File-Protect Bit

Revised: 10/16/91
Security: Everyone

MultiFinder: How to Set File-Protect Bit

=====

Article Created: 2 March 1989
Article Last Reviewed: 16 October 1991
Article Last Updated: 16 October 1991

TOPIC -----

I have a problem with the file-protect bit under System 6.0.2 and MultiFinder. After setting the file-protect bit with ResEdit, I can still copy or delete the protected file.

DISCUSSION -----

If you have a folder's window open under MultiFinder and change the file-protect bit for a file in that folder, you can still copy the file even though the file-protect bit is clearly set.

However, if you set the file-protect bit for that file and then close and reopen the folder, you will not be able to copy the file.

This is because the directory information for the folder resides in memory, while the folder is open. Thus, the changes written to the disk at the time of the file-protect update are not updated in the copy in memory. Closing and opening the folder causes the directory information to be copied into RAM with the appropriate values.

This applies to an HFS disk, too. To solve this problem you must unmount the HFS disk by dragging it to the trash, then reinsert it.

Synchronous Terminal Emulation on the Macintosh

Revised: 5/10/89
Security: Everyone

Synchronous Terminal Emulation on the Macintosh

=====

This article last reviewed: 2 March 1989

There are many ways that synchronous communications can be performed on a Macintosh. The type of hardware and software needed is usually linked to the type of host computer that you want to connect to. Also, the hardware performs the synchronous interface, rather than the terminal emulator itself. The software must be able to communicate with the specific hardware: most of the time, each particular type of synchronous communications hardware has software written specifically for it.

For instance, MacTerminal can be used for synchronous communications with an IBM host through the use of an AppleLine protocol converter, but other standard Macintosh terminal emulators can NOT be used in the same fashion. It is the AppleLine that actually performs the synchronous communications, while MacTerminal is communicating asynchronously with the AppleLine.

Macintosh: Troubleshooting Frequent System Crashes (4/94)

=====

Article Created: 2 March 1989
Article Reviewed/Updated: 5 April 1994

TOPIC -----

This article documents some troubleshooting steps if your Macintosh is suffering unusual and periodic crashes.

DISCUSSION -----

1) These types of problems are caused most commonly by conflicting extensions (INITs) or control panels in the System Folder, a corrupted System file, or software that is incompatible with your System and its combination of extensions and control panels. Check for a pattern in the crashes and the exact configuration of the system (extensions and control panels being used, for example). Noting the times at which the crashes actually occur, and the specific series of steps needed to reproduce them, are vital to pinpointing a possible software problem.

2) If you have a large amount of hardware (large monitors, printers, scanners, etc.), it is possible that you are overloading the circuit on which you are running your equipment. For instance, the LaserWriter II itself draws more than 7 amps. Most circuits are only 15-amp circuits, so this doesn't leave much for the Macintosh, large display monitor, scanner, and external hard drive. Thus, it is possible that you are getting low voltage situations. Such situations can cause unusual or periodic crashes. If you have specific hardware problems, like failing hard drives, investigate the electrical circuit as the source of the problem.

For more information, search under "Troubleshooting".

LaserWriter: Maximizing Accurate Print Registration

Revised: 5/11/89
Security: Everyone

LaserWriter: Maximizing Accurate Print Registration

=====

This article last reviewed: 2 March 1989

When printing to a LaserWriter, the accuracy of the print location (the consistency of location of lines and letters from one printed sheet to the next) is based partly upon these variables:

- 1) The weight of the paper being used (16 to 24 lbs. recommended, 20 lbs. preferred). If the paper weight is less than 16 lbs., paper pickup and registration through the paper feed mechanism will probably suffer. If the paper weight is more than 24 lbs., there will probably be paper jams due to poor paper pickup.
- 2) Paper finish (photocopy or typewriter bond preferred). If the finish of the paper stock is smooth, then the paper may slip or be skewed due to poor or uneven feed roller adhesion.
- 3) Age and use of the LaserWriter. The older a LaserWriter is, and the more heavily it has been used, then the higher the chances are for poorer print registration. This is due to the wearing of the paper feed roller and accumulation of paper dust. These factors cause the paper to slip slightly during paper pickup and feed. Regular cleaning of the paper pickup and feed rollers should eliminate some of the registration problems.

Macintosh II and Macintosh SE: Sound Level Differences

Revised: 9/16/93
Security: Everyone

Macintosh II and Macintosh SE: Sound Level Differences

=====

Article Created: 11 May 1989
Article Reviewed/Updated: 8 June 1992

TOPIC -----

What are the differences in sound level between the Macintosh SE and Macintosh II?

DISCUSSION -----

There is a significant difference in the sound output of the Macintosh SE and the Macintosh II -- as much as a difference of 14dB in output level for the same digitized sine wave -- because of differences in output strength at the sound jack.

The explanatory information is in the "Macintosh Family Hardware Reference Manual" (Addison-Wesley, ISBN# 0-201-19255-1).

Macintosh SE Sound Circuit:

The external sound line provides a low-impedance, high-level (8VAC peak-to-peak) signal that can drive any load of 32 or more ohms.

(WARNING: The signal available at the external sound jack on the Macintosh SE computer is capable of damaging some power amplifiers and can generate dangerous sound levels in headphones. You should use extreme caution when using this signal with amplifiers or headphones.)

Macintosh II Sound Circuit:

The external sound jack is at standard line level (approximately 1.5VAC peak-to-peak), and its source impedance is approximately 47 ohms. The jack is capable of driving a headphone load of 8 to 600 ohms, or the input to almost any audio amplifier or amplified speakers. It will NOT adequately drive a directly connected external speaker.

Based on this information, with the same volume setting on each machine, regardless of the input impedance of the audiometer, there will be a large difference in the sound level output.

One possible method of equalizing these signals would be to construct a box with a switch. When using a Macintosh SE, you could switch in either a fixed resistor or a potentiometer to drop the audio input level to the audiometer. The other switch position would be straight through from the Macintosh II. This level-matcher would be completely passive in nature, and could be built relatively inexpensively.

LocalTalk Has Effective Electrical Isolation

Revised: 5/11/89
Security: Everyone

LocalTalk Has Effective Electrical Isolation

=====

This article last reviewed: 8 March 1989

The LocalTalk system is much less sensitive to power problems than many networks.

To start with, LocalTalk uses differential signaling, which has a higher noise immunity than normal, directly-connected TTL logic networks (like Corvus, for instance). Also, LocalTalk uses transformer coupling from the network to the node. This provides additional isolation from noise on the network. The transformer specification requires that there be no significant leakage current with 1000VDC applied between the secondary winding and the core.

Because the LocalTalk network is passively coupled, any severe noise spikes would have to come through the system itself. This means any protection provided for the system itself would also be protecting the network.

Graphical Data Display Manager (GDDM): File Format Specification

Revised: 5/11/89
Security: Everyone

Graphical Data Display Manager (GDDM): File Format Specification

=====

This article last reviewed: 8 March 1989

GDDM, Graphical Data Display Manager, is a graphical, character-encoding scheme used for displaying graphics. Two other graphic display schemes are Vector and All Points Addressable (also known as "APA" or "Raster").

Using GDDM to display a box on a display screen might consist of sending four character codes. You might expect the four codes to consist of two parallel-horizontal lines and two vertical-parallel lines, all with end points touching. But instead, one of the character codes might look something like the letter "L". The second would be an "L", but flipped upside down. The third would look like an "L" flipped horizontally, and the fourth character would display like an "L" flipped vertically and horizontally.

Therefore, these "L"s could be used to construct a rectangle on the display. GDDM uses a variety of graphical characters, some looking like "L"s, to construct graphical displays.

Vector graphics, of course, define lines bound by two points. APA (Raster) graphics provide control of every point.

Inter•Poll: How to Identify Active Apple II Systems

Revised: 3/1/93
Security: Everyone

Inter•Poll: How to Identify Active Apple II Systems

=====

This article last reviewed: 17 March 1989

Certain requirements must be met before Inter•Poll can identify an Apple II on a network:

Apple IIGS

For an Apple IIGS to appear in the "Device List" window of Inter•Poll, you must:

1. Select "Built-in AppleTalk" from the Control Panel. At the same time, set the port that the network is connected to, generally the Printer port, to "Your Card".
2. Shut down and restart the system.
3. Run Inter•Poll on the Macintosh, or have it running and checking the network. The Apple IIGS should show up in the Device List window.

Apple IIe

1. Install Apple II WorkStation card in slot 7 of Apple IIe and connect LocalTalk port to network.
2. Start up system and log into a ProDOS server on the network. Once the system gets past the Password screen, the device shows up in the Device List window of Inter-Poll.

The important requirements are:

- Having Built-in AppleTalk selected in the Control Panel of the Apple IIGS
- Having the proper port set to "Your Card" on the Apple IIGS

- Being past the Password screen on an Apple IIe with WorkStation Card.

AppleShare Network Server 2.0.1: Installation & Error Message

=====

Article Created: 23 March 1989
Article Reviewed/Updated: 5 October 1993

TOPIC -----

Here are a few tips on troubleshooting AppleShare Network Server installation problems:

DISCUSSION -----

Installing System 6.0.2

Under 6.0.2, the Server Installer disk appears to install normally, but when you launch Admin on the Server Administration disk you get a message: "FINDER IS OLDER VERSION".

The easiest solution is to copy Admin into the Server Folder on the hard drive and start it from there.

No "Apple II" Menu in Server Administration

APPLE II does not appear as a menu choice, until the "Apple II" box is checked in SERVER INFO under the SERVER menu. When that box is checked, Apple II users' folders and a folder called SYSTEM for the Apple IIs are created. You must restart the server before the Apple IIs will start up from the server.

No Boot Server - Apple IIGS

Check the Control Panel on the Apple IIGS. Under the Slots section, SLOT 1 should be YOUR CARD, SLOT 7 should be AppleTalk, and START-UP SLOT should be set to SCAN.

Access Not Allowed

This message can take several forms, but the basic content is always that a

user does not have access to a particular file or folder.

In fact, users should see this whenever they try to get to something they shouldn't. If access should be allowed, check the access privileges of all the folders involved, either under SERVER ADMINISTRATION, or using a Macintosh SE logged on as "Administrator".

Access Privileges Are Not the Same as You Set Them

To save time, a person setting access privileges may choose an option on the ACCESS PRIVILEGES box called CHANGE ALL ENCLOSED FOLDERS. If you do this, you change the owner of the enclosed folders, the group designation, and the access privileges. Once this is done, you must go back in and change each of the folders back to the correct owner, group, and access privileges.

No ProDOS Memory Card Found

On the Apple IIe, this means exactly what it says -- you need a ProDOS memory card. Typically, an Apple IIe requires 128K to be a workstation and 512K to be a teacher station.

On the Apple IIGS, this means either not enough memory or, more commonly, that you need to set up a RAM disk using the Control Panel. If you have the current ROMs, a 256K RAM disk will suffice, but 512K is probably better.

No Users in Aristotle

When Aristotle menu management starts, it creates a user list. If no user list is found, it is normally because the groups "STUDENT" and "TEACHER" are not found. Remember, the group names must be exactly "STUDENT" and "TEACHER". Names like STUDENTS and TEACHERS, or STUDENT GROUP and TEACHER GROUP will not work. Many times, groups still appear correctly in Admin, but recopying the primary group into the User Information folder will correct the situation. CHANGE ALL ENCLOSED FOLDERS is often the culprit here.

(Important Note: STUDENT and TEACHER must be the Primary group.)

A User Still Doesn't Appear After Re-doing Group

If a student or teacher doesn't appear in Aristotle after restoring their group designation, delete the user and then recreate it.

You Must Be a Teacher To Use This Program

Aristotle menu management can be used only by users whose primary group is TEACHER. Check the user's primary group.

How Can I Keep Users From Copying Files to Floppies?

Under the FILES AND FOLDERS menu, choose GET INFO on the program file in question. In the upper-right corner there is a box named COPY-PROTECT. When

this box is checked, users cannot make copies of the file.

How Can I Keep Users From Hiding Other Users' Folders, Trashing Them, Etc.?

Again, under the FILES AND FOLDERS menu, open the GET INFO on the folder. In the upper-right corner there is a box named LOCKED. With this box checked, no one except the owner can move a folder, throw it away, or rename it.

Volume Name Must Be a Legal ProDOS Name

For Apple IIs to be able to use a server as a volume, the volume must have a legal ProDOS name. Unfortunately, this message usually appears when you check the APPLE II ADMIN box under the SERVER INFO menu, and there is no handy way to change it. Go back to the Finder and change the name of the disk.

Remember, a name has a maximum of 15 characters, no spaces, starts with a letter, and contains only letters, numbers, and periods.

Illegal ProDOS Name That Appears To Conform to Rules

Check for blanks preceding and/or following the volume name.

AppleTalk Must Be Installed

This usually occurs on a workstation and not the server. In either case, go to the Chooser and select the radio button that makes AppleTalk ACTIVE.

Administration Is an Unavailable Option

If Administration is an option that cannot be selected, then it does not reside in the server folder. This means someone probably copied the ADMIN program onto the hard drive, but not into the Server Folder. Go back to the Finder and drag it into the Server Folder.

Administrator Cannot Use All Folders

This normally occurs when using a Macintosh SE as a workstation logged on as Administrator.

If the Administrator is unable to see any folders or to change names, privileges, and so on, then Administrator was not given all privileges. Go to the SERVER ADMIN program, open the ADMINISTRATOR's user information, and check the ALL PRIVILEGES box.

Error/Unable To Load Application

On an Apple II running Aristotle, these messages appear when pathnames are incorrectly stated when creating an application for the application list. Aristotle WILL NOT catch this in menu management, but only when a user selects the menu option and tries to load the application. Correct the pathname. It should appear as follows:

/volumename/directory1/directory2...../application

Aristotle... Not Saved Properly

This message occurs when a student logs on, but the teacher has not saved and quit Aristotle menu management. Have the teacher save any unsaved work and quit Aristotle.

Startup Configuration Not Properly Setup

This message occurs when access privileges to start-up files and folders have been corrupted. Check access privileges for the folders Aristotle, MENU.D, and DISPLAY, if the student is using Aristotle.

Garbage When Printing to the LaserWriter

To use the LaserWriter, an ImageWriter emulation program must be downloaded to it. You can do this by printing to the spooler or selecting the printer again in the Chooser.

System 6.0.2: How To Protect Files

Revised: 5/31/89
Security: Everyone

System 6.0.2: How To Protect Files

=====

This article last reviewed: 23 March 1989

Users of System version 5.0 may have found changes in file privileges under System 6.0.2 -- namely, that any files locked using System 5.0 can now be trashed, removed, or moved to another folder.

Under System version 5.0, setting the protect bit on a file causes the following under the Finder:

- The file cannot be moved from its current folder/window.
- The file cannot be thrown in the trash.
- The file cannot be copied.

When any of these were tried, the Finder gave the message: "That may not be duplicated or moved."

Under System version 6.0.2, setting the protect bit on a file only prevents the Finder from copying the file. The file can be moved or thrown in the trash. The message returned by the Finder when you try to copy the file is: "That may not be duplicated or copied."

The change in the wording of the dialog box indicates to us that this was an intentional change and that we can expect this to be the new function of the protect bit.

You can keep a file from being thrown in the trash by setting the locked bit, but the file can still be moved. Also, the locked bit is much more easily changed than the protect bit. We know of no way under System 6.0.2 to prevent a file from being moved under the Finder.

SCSI Troubleshooting: Hardware and Software Conflicts

Revised: 5/17/89
Security: Everyone

SCSI Troubleshooting: Hardware and Software Conflicts

=====

This article last reviewed: 30 March 1989

Connecting SCSI devices to the bus and installing their associated drivers and INITs sometimes raise interesting issues. Improper termination is typically the root of hardware conflicts. A less likely reason is forgetting to set the SCSI priority number to a unique number, or using a device that improperly "provides" built-in termination, or improperly powers the terminators. Do not overlook damaged cables, terminators, or the terminator power source.

The system could also be running out of memory. Configuring a start-up disk with minimal drivers and INITs or adding more RAM may help test that theory.

Software conflicts typically result from INITs clobbering one another at startup, possibly due to poor memory management. Often, you can isolate a troublesome INIT by removing all extraneous INITs, then systematically adding each one back into the System Folder, one at a time, until you can no longer start up or use a device.

Also, you can often eliminate the conflict by renaming the INIT (or files that contain INITs in their Resource Fork) so that they install in a different order. (INITs and drivers are installed alphabetically.) For example, you could rename the Apple Scanner INIT to "aScanner" to get it to load sooner.

Note that there are some INITs (like Dyna File) that won't work if renamed. If this is the case, and the INIT conflicts with the Apple Scanner, you may have to remove the INIT from the System Folder when you're going to use the Apple Scanner.

LaserWriter: How to Turn Off the Test Page on Startup (10/94)

=====

Article Created: 6 April 1989
Article Reviewed/Updated: 12 October 1994

TOPIC -----

Normally, your LaserWriter prints a test page every time you turn on its power. This is the page with a large ampersand and other printer configuration facts on it. This article describes how you can disable this test page.

DISCUSSION -----

You can inhibit the LaserWriter from printing a test page every time it's powered up.

With a Macintosh
=====

Use the LaserWriter Utility (System 7.0 or higher) and select "Set Startup Page..." from the Utilities menu. You are presented with an option to turn the Startup Page On or Off.

With an MS DOS Based System
=====

A boolean value called dostartpage is stored in the persistent parameters of all LaserWriters. You change this value with these PostScript programs:

Disable Startup Page PostScript Program

This program disables the printing of a start-up page:

```
serverdict begin 0 exitserver
statusdict begin false setdostartpage
```

Enable Startup Page PostScript Program

This program enables the printing of a start-up page:

```
serverdict begin 0 exitserver
statusdict begin true setdostartpage
```

These programs can be sent via a PostScript downloading program, a word processor that supports straight ASCII output (no imbedded control codes), or entered while in PostScript Interactive mode.

TOPIC -----

Under System 6, is it possible to start the Finder, MultiFinder, and A/UX from a HyperCard stack - IF HyperCard is the start-up application, and that stack is the start-up stack?

DISCUSSION -----

Here are some things you have to do to make this work:

- Change the file type of MultiFinder to APPL. HyperCard only runs applications (or documents belonging to applications) when you use HyperTalk's Open command. Changing MultiFinder's file type to APPL makes it an 'application'.
- Make sure that no INITs are loaded if you want A/UX to be run. The sash application that launches A/UX 1.0 or 1.0.1 does not coexist with most INITs.
- Make sure that the launch command in the sash application is configured to launch from the proper drive if you are using more than one hard disk on this machine.
- Within HyperCard, you need to decide whether you will include a card on the Home Stack that does the launch, or if you will use the start-up script in the Home stack to open another stack that does the launching.

Apple HD Backup Error: Tried To Open Too Many Files

Revised: 6/15/92
Security: Everyone

Apple HD Backup Error: "Tried To Open Too Many Files"

=====

Article Created: 25 January 1989
Article Last Reviewed: 20 May 1992
Article Last Updated: 20 May 1992

Note: HD Backup is not compatible with System 7; this article is relevant only for those running System 6.0.x or earlier.

When using Apple's HD Backup, you may get a "Tried to open too many files" error with "Cancel" or "Continue" options. When you click on continue, it goes on to the next file, and then produces the same error.

Such an error message suggests files being backed up are "busy". This may be due to:

- Finder file information flags set incorrectly.
- Damaged system software.
- Maximum number of files allowed set unreasonably low in boot blocks.
- A problem with HD Backup, which Apple's testing could not duplicate.

Resetting the file information flags can be done by "repairing" the hard disk (hold down Command-Option as the volume is mounted).

To fix a system software problem, or ensure the number of files allowed is reasonably set, reinstall the system from known good System Tools disks, preferably by dragging the old System Folder to the trash, and then using the Installer to install new software.

There is no specific limit to the size or type of a hard disk you're able to back up with Apple HD Backup, only a practical one. To back up an 80MB hard disk, you need more than 100 diskettes, and a lot of time and patience for inserting and removing that many diskettes. Theoretically, you could back up much larger drives, 1.5 gigabyte drives for instance, but we haven't tested

that capability or know of anyone who is likely to need or want that feature.

Numerous third-party alternatives to HD Backup exist.

A/UX: Ethernet TDR Test Results, Shorts (8/94)

Revised: 8/24/94
Security: Everyone

A/UX: Ethernet TDR Test Results, "Shorts" (8/94)

=====

Article Created: 8 December 1988
Article Reviewed/Updated: 23 August 1994

TOPIC -----

If you run a Time Domain Reflectometry (TDR) test on a thin Ethernet network, all the A/UX systems (and only the A/UX systems) may appear as what seem to be shorts -- whether the systems are powered on or off.

Since the systems appear to be shorts even when powered off, the problem is almost definitely not A/UX-specific.

DISCUSSION -----

When a thin Ethernet was tested with Macintosh II or IIX (with the systems both powered on and powered off) the Macintoshes did not appear as shorts during any of Apple's TDR tests -- however, the TDR did show minor disturbances for each of the EtherTalk cards on the network.

Although these disturbances are within specifications when compared to other types of Ethernet connections, they might be interpreted as shorts. Since the network is otherwise operational, the problem described above may be due to the interpretation of the TDR results or to the TDR itself having been improperly configured.

If the TDR sees disturbances other than what appear to be shorts, it is not reporting shorts. Try deliberately shorting one of the connections (temporarily) to see exactly what a short looks like, and how it affects the TDR display.

A/UX: Tape Driver and 8K Buffer Limitation (8/94)

=====

Article Created: 12 March 1989
Article Reviewed/Updated: 23 August 1994

TOPIC -----

People writing their own A/UX device drivers for a tape backup should be aware of a limitation on the physical I/O buffering between the kernel and the tape cartridge driver.

As an example: a fixed, 8K, physical, I/O buffer was built into the kernel. As a result of this limitation, any calls to "physio" split 64K blocks of data into 8K chunks. Any attempt to pass 64K to "physio" will result in 8 passes of 8K instead of one pass of 64K.

Macintosh: Connecting With the Unisys A4FX Mainframe

=====

This article last reviewed: 12 March 1989

If you need to upload and download files between a Macintosh and an Unisys A4FX mainframe, consider Avenue Software's Contact product. If the connection is asynchronous, you only need the software. If not, you will need their TDI/RS-232 converter, too. Multiple station connectors are available at a lower cost per workstation price. (Avenue Software specializes in terminal emulator and data transfer software for transferring files to/from Unisys mainframes.) For more details, search the Tech Info Library under "Avenue Software".

A/UX 3.0: Maximum File Name Length and POSIX (8/94)

=====

Article Created: 12 March 1989
Article Reviewed/Updated: 19 August 1994

TOPIC -----

This article discusses the maximum file name lengths for A/UX 3.0, POSIX, and BSD 4.3.

DISCUSSION -----

A/UX 3.0 is based on System V Release 2, Version 2 version of UNIX. File names can be up to 255 characters in length.

POSIX, on the other hand, defines file name length in the constant MAXNAMLEN in the "/usr/include/dirent.h" header file. A/UX is certified by the National Institute of Standards and Technology as compliant with FIPS #151 (IEEE POSIX 1003.1-1990, and ISO 9945-1)

The BSD 4.3 maximum file name length is 255 characters. However, the implementation of file system between the BSD UNIX and the System V UNIX is completely different.

The BSD fast file system for A/UX was been requested and has been implemented in A/UX.

AppleScan: Workarounds For Common Problems

Revised: 5/24/89
Security: Everyone

AppleScan: Workarounds For Common Problems

=====

This article last reviewed: 27 February 1989

Here are four useful workarounds for common Apple Scanner problems:

17-Character File Name Limitation

This file name limitation applies to half-tone pattern names and setting names (for example, Untitled Pattern 2). To work around, delete any setting names or half-tone pattern names that exceed the limit. Note: You only get the system error when saving the file in PICT format.

Background Printing

Background printing of scanned images under MultiFinder can produce "streaks". This applies to AppleScan and to other applications that print scanned images. The cure: Turn off background when printing a document that contains scanned images.

Printing Scanned Half-Tones

In general, printed output of scanned half-tones looks best when the Graphics Smoothing, Faster Bitmap, and Precision Bitmap print options are turned off. This applies to most applications. Use LaserWriter Driver 5.2 (included on the AppleScan disk) and the System 6.0 Printing Tools disk.

HyperScan

When starting HyperScan, a "Can't load Global variables" dialog may appear, preventing use of the stack. This occurs in low-memory situations on 1MB systems. Try turning off the RAM cache. If the problem persists, an INIT (or several INITs) may be using too much memory.

Filming a Macintosh Screen Without Flicker (11/94)

Revised: 11/7/94
Security: Everyone

Filming a Macintosh Screen Without Flicker (11/94)

=====

Article Created: 14 March 1989
Article Reviewed/Updated: 07 November 1994

TOPIC -----

This article describes how to film a Macintosh screen without flicker, using a film (movie) camera, rather than with a video camera. A separate article describes filming a Macintosh screen with a video camera. In all cases, you must use a multisync monitor for the Macintosh II to view the screen after these modifications.

Read the entire article, including warnings, before beginning any procedures described here.

DISCUSSION -----

The techniques given here set up a camera to record the manually genlocked screen. The clock slows the screen updates exactly to the camera frame rate. This makes it possible for all of the horizontal scans to be present during each frame of the camera. The key issue is to slow the video card's video signal. You can do this either by replacing the 30.24MHz clock or by connecting an external signal generator.

WARNING: Any hardware modifications to the video card void the warranty of the video card. Apple Computer does not support any modification to the video card.

CLOCK REPLACEMENT METHOD

To slow the video signal, remove the oscillator from the card and substitute a 5-volt, square-wave, pixel-clock signal at the desired level of 21.77580 MHz. This synchronizes the camera to the screen. However, a visible horizontal/vertical retrace line might appear from the small offset of the two timings.

The clock controls the time period of each pel (displayed picture element) and all display control signals, like the sync (synchronization) signals. For a 48Hz

noninterlaced screen (progressive scan), the Macintosh II video needs an oscillator (pixel clock) of 21.77580 MHz.

Notice that a clock is not the same as the sync. The vertical sync and the horizontal sync are normally 66.67Hz and 35KHz, respectively, on a Macintosh II video card.

THE EXTERNAL PROGRAMMABLE SIGNAL SYNTHESIZER METHOD

The best method is to use an external programmable signal synthesizer (generator) that can be set to the adjusted setting and stored in memory. These units can be found at electronic test-equipment rental houses.

If you do not want to remove the clock, you can ground pin 14 of the J3 connector on the card (pins 1, 2, 3, 5, 7, 9, and 11 of J3 are grounds) and connect the external clock from the signal synthesizer to pin 4 of the J3 connector. This causes the external clock to be selected over the Macintosh II Video Card's 30.24-MHz oscillator. The generator must be on for the video card to function. This method also voids your warranty and is not supported by Apple Computer. The pinouts and signal description of the Macintosh II Video Card can be found under "Macintosh II Video Signals".

Note: The J3 connector is not the external port, but a connector on the video card. Usually, it is located under the serial number sticker.

You must set the synthesized clock signal to 22MHz and wait for the scrolling scan bar (as viewed through a camera) to move off the screen. When you see this, set the signal synthesizer to the proper clock timing of 21.77580 MHz.

Appropriate signal synthesizers include the Wavetek 178 Frequency Synthesizer and the Hewlett Packard 3336C or 8340A. The Wavetek 178 has a resolution of 8 significant digits. This allows for the 21.772800MHz square-wave, 5-volt, pixel clock. To sync the vertical retrace line, the operator sets a 22MHz time in memory. The 22MHz causes a slow scroll of the vertical retrace line. When the line is off the screen in the blanked portion of the screen, the operator executes the 21.772800MHz clock from memory.

Macintosh: RS-422 and RS-449 Communications at 56K Baud

Revised: 8/25/89
Security: Everyone

Macintosh: RS-422 and RS-449 Communications at 56K Baud

=====

This article last reviewed: 23 August 1989

RS-422 is a subset of RS-449 signalling. Therefore, the two can be directly connected with no external interface needed.

RS-449 is a combination of RS-232, RS-422, and RS-423 and, as such, contains all the characteristics of these existing standard communications methods. RS-449 has additional connections for greater control over the interchange of data than previously existed with the current standards. Because RS-449 can use differential signalling (as used in the RS-422 interface), the data rate is higher than that imposed by RS-232 and single-ended signalling.

To communicate at high Baud rates (like 56K) through the serial port, take a look at the following software packages:

- MicroPhone II(from Software Ventures)
- VersaTerm-Pro (Peripherals, Computers, and Supplies Inc.)
- DynamComm (FutureSoft)

Note: V.35 is a 48 Kbit, baseband system, operating in the 60 to 104 KHz group band, over a modem. It is not directly compatible with the serial data output from a Macintosh.

A/UX Response To Callback

=====

Article Created: 6 April 1989

Article Change History

08/31/92 - REVIEWED
o For technical accuracy.

TOPIC -----

If you need to dial into your A/UX computer and want it to dial you back before proceeding, try these steps and the example script that follows:

DISCUSSION -----

- 1) Using "cu", "kermit", or other means, login into the remote UNIX machine.
- 2) Exec a program or a shell script saying "callback"; the "callback" should perform the following tasks:
 - Logout your current terminal session, hang up the phone line, put the originating modem in the listen mode, and set the proper TTY bits mode to be used as a dial-out port.
 - Wait a couple seconds, clear the phone line, and dial the phone number the user provided.
 - Do an "exec /bin/login" to respawn a login session.

Here is a short example of "callback" in a C Shell script. You may need to fool with the "stty -hupcl" command; do not hang up the modem on the last close. This example assumes that the remote modem is a Hayes or Hayes-compatible modem.

```
#!/bin/csh
if ($#argv != 1) then
    echo "Usage: callback YourHomePhoneNumber"
    exit
endif
set user=`whoami`
set number=$argv[1]
grep "$number" /usr/adm/callback.phones > /dev/null
if ($status == 1) then
    if ($user != root) then
        echo 'You are not allowed to use dialback because your phone'
        echo 'number can not be found in the dialout-phone list.'
        echo 'Please check the number and try it again.'
        exit
    endif
endif
# verify if it is a login shell
set pid=`ps -u$user |grep -c csh`
if ($pid[1] != 2) then
    echo "not login shell, pid=$pid"
    exit
endif
onintr we-are-back
set nohup
stty -hupcl -echo intr ^C
echo "Please hang up the phone. Or just turn the modem OFF and ON"
echo "I'll call you back in about 20 second."
sleep 15
echo -n x | tr "x" "\015"
sleep 2
echo -n x | tr "x" "\015"
sleep 2
echo -n x | tr "x" "\015"
sleep 4
echo -n "ATDT $number"
sleep 4
echo $*
# While you're waiting, log the usage of this script.
set dt=`date`
echo $dt[2-4] $user ' ' $* >> /usr/adm/callback.log
sleep 20
unset nohup
we-are-back:
stty hupcl echo
echo "HIT <Control-C>"
```

The above script has been tested and worked between a Macintosh SE (running MacTerminal) and an A/UX 1.0 system. You can modify it if it doesn't work on your system.

A/UX: ed and Filenames

Revised: 9/18/92
Security: Everyone

A/UX: "ed" and Filenames

=====

Article Created: 16 March 1989

Article Change History

08/31/92 - REVIEWED

- For technical accuracy.

TOPIC -----

Some A/UX users have misunderstood how the "ed" program works in terms of remembering file names.

DISCUSSION -----

In the following illustration the user tries to edit a file named "testfile", insert the contents of the password file, and update the original file.

\$ ed - testfile	
P	Get a prompt
* 3	The original script inserted a file at line 3
-r /etc/passwd	Include the password file
w	Try and update the original
?	'ed' has a problem!
h	Explain it.
cannot open file	It can't write to the /etc/passwd file
f	Show the "current" file
/etc/passwd	It's set to /etc/passwd not to "testfile"!
q	
\$	

The user assumed that the file name at the end should be "testfile" and not "/etc/passwd".

The manual entry for ed(1) gives an explanation for this problem. The currently remembered filename can be set when you use certain commands within ed--"r FILE", for example. There are some restrictions; the currently remembered filename is only changed when FILE is the very first filename mentioned since ed was invoked. So when you add a command like

```
f testfile
```

directly after invoking ed, the currently remembered filename will be "testfile" until you specify otherwise. This way the "r" command will not set the filename.

The ed(1) manual pages do mention some restriction on the currently remembered filename. Paragraph of (\$) r file command, states

"The currently remembered filename is NOT changed unless the file is the very first filename mentioned since ed was invoked."

AST Mac286 Version 2.0 Software Features

Revised: 5/24/89
Security: Everyone

AST Mac286 Version 2.0 Software Features

=====

This article last reviewed: 14 March 1989

The new version 2.0 of the AST Mac286 Software (downloadable from the AST BBS) has some new features:

- MultiFinder Support. Run DOS and Macintosh Programs at the same time. Mac286 has an option to maximize DOS performance or let your other applications and AST more equally share the 68020.
- Better support for color and graphics modes. CGA mode is faster and both modes (CGA and Mono/Hercules) now support character highlighting. (This should make 1-2-3 easier to use.)
- The D: Drive software has been enhanced to support subdirectory access. Accessing files in directories other than the selected directory in v1.01 did not work and caused some operational problems when using networks to run DOS applications.

Other new functions included in the update are:

- Copying and pasting graphics from the PC to a Macintosh application
- Postscript Printing to LaserWriters over the AppleTalk network system
- Improved Mouse Support for PC applications

AST will update all registered users.

LaserWriter: Problem Printing on Second Side

Revised: 12/6/89
Security: Everyone

LaserWriter: Problem Printing on Second Side

=====

This article last reviewed: 14 March 1989

Some people have had a problem printing two-sided pages on a LaserWriter. The pages print fine on the first side, but when printing on the second side, the ink smears at the top and the bottom of the page. There is no problem when the paper is manually fed into the printer. This can happen even when you're not using special paper.

The probable cause of the smearing or smudging is the fact that LaserWriters fuser rollers have a small amount of lubricant on them. The second pass may pick up some of this lubricant, causing the problem.

Your best bet is to experiment with other paper stock until you find one that is less sensitive to the minute amount of lubricant. Consider using paper that is specifically designed for use with photocopiers or laser printers. Definitely avoid the Xerographic paper that is designed to have the image placed strictly on one side. For more details on papers, search the Tech Info Library under "James River", "Scotch", and "Avery".

Network Performance and Statistics

Revised: 5/24/89
Security: Everyone

Network Performance and Statistics

=====

This article last reviewed: 7 April 1989

A user, curious about network performance, put TrafficWatch on a PhoneNET network consisting of 18 Macintoshes, several LaserWriters, a Kinetics FastPath 4, and a MicroVAX running AlisaShare. Some typical statistics (with a sampling period of 15 minutes) are as follows:

Total Packets:16451
Timeouts:39
Overruns:12
CRC Errors:0
Length Errors:39

Total Packets:13030
Timeouts:35
Overruns:8
CRC Errors:0
Length Errors:33

Total Packets:16017
Timeouts:28
Overruns:14
CRC Errors:0
Length Errors:29

Total Packets:40672
Timeouts:103
Overruns:43
CRC Errors:1
Length Errors:98

Total Packets:50355
Timeouts:304
Overruns:37
CRC Errors:0

Length Errors:310

Total Packets:33312

Timeouts:78

Overruns:24

CRC Errors:1

Length Errors:77

To date, no rule-of-thumb indications for good or bad network performance have emerged. In general, network engineers consider ratios to be less important than individual categories.

In fact, their recent tests yielded results comparable to those given here. Typically, CRC errors were low or zero. Other types of errors seemed to vary in proportion, depending on the type of network traffic and the specific network.

The worst case in the sample above is a little more than a 1 percent error rate. In most of the samples, you were closer to 0.5 percent. This is certainly acceptable for a network with the number of machines in this example--18 Macintoshes, several LaserWriters, and a FastPath on a single network and zone. This is close to the size that calls for breaking up the network by adding bridges. As you add devices or see increased network use (in its current configuration), the error rate would likely increase.

LocalTalk PC Card and PC-Compatibles: Compatibility Issues

Revised: 8/28/90
Security: Everyone

LocalTalk PC Card and PC-Compatibles: Compatibility Issues

=====

This article last reviewed: 27 March 1989

With the number of PC-compatible workstations growing, questions have arisen concerning the compatibility of these workstations with the LocalTalk PC card and AppleShare PC. This article describes the issues surrounding the card.

Bus Speed

Most PCs or compatibles have an 8 MHz bus. Some compatibles run their buses at a faster rate and have a mode to slow the bus speed. Those that do not have this slower mode find a great many cards are not compatible, because most cards are designed for compatibility with the IBM-PC 8MHz bus. The LocalTalk PC card has been tested successfully for 8-MHz compatibility. However, faster bus speeds produce reports of incompatibilities.

DMA

The LocalTalk card works with either DMA channel 1 or 3. One of these DMA channels must be present and available on the PC or compatible.

Control Signal Address Ranges

The LocalTalk card uses the address ranges \$240-\$247 or \$220-\$227. One of these ranges must be available.

Software Compatibility

AppleShare PC is compatible with most software. Some packages, while running, don't allow the DA pop application to appear. These packages are capturing either the keyboard command or holding the operating system in a state where the DA cannot appear. In these cases, the DA usually sounds a beep. The only method of using the DA is to set up connections or make configuration changes in the DA prior to running these applications.

Also, some printer utilities reroute the printer ports for spooling, buffering, or emulation. These may not work with AppleShare PC, may cause problems, or may even cause the PC to hang.

GS/OS: Bard's Tale II Format Incompatibility

Revised: 5/25/89
Security: Everyone

GS/OS: "Bard's Tale II" Format Incompatibility

=====

This article last reviewed: 27 March 1989

The Electronic Arts' program "Bard's Tale II" does not recognize a disk formatted under GS/OS. The game requires the user to format a disk that will store the character player information and statistics. When formatted under GS/OS, the disk is not recognized as a ProDOS disk. Electronic Arts has verified that the problem exists regardless of what format options are chosen.

The only workaround is to format using an earlier version of System Software, like 3.1. Here's why...

The ProDOS format has not changed. The information stored in the directory blocks has changed. The change consists of including additional information in the directory structure than in previous versions of ProDOS. The additional information is fully documented in the description of ProDOS/16 directories and is correctly handled by ProDOS/16 directory access routines.

"Bard's Tale II" reads these directories without calling the ProDOS routines. Their program only understands the information previously stored in the directory, despite the documentation for future expansion to the directories. Programs that use the ProDOS calls to access the directory continue to work.

Using earlier versions of ProDOS (v3.2 or earlier) will not write the additional information to the directory and make it possible for "Bard's Tale II" to read the disks. The problem is purely a compatibility issue due to the implementation of accessing files in "Bard's Tale II".

AppleShare PC 1.1: Not Enough Memory For Installation

Revised: 5/24/89
Security: Everyone

AppleShare PC 1.1: Not Enough Memory For Installation

=====

This article last reviewed: 27 March 1989

Some users have had problems installing AppleShare PC 1.1. Here is a typical example:

The user has a Compaq 386/25 running DOS 3.3. The Compaq is configured with 640K base memory and 1280K extended memory and the following expansion boards: LocalTalk PC, Paradise EGA, Targa 16, and Compaq Multifunction controller board.

The user planned to have the Compaq and another PC share a LaserWriter IINT. After installing AppleShare PC, there is not enough memory to run applications. The memory problem is so severe that there was not enough memory to attach the LaserWriter through the DA.

In solving this type of problem, first consider how AppleShare PC uses memory. There is an AppleLink article titled "AppleShare PC Memory Use" in the Tech Info Library that describes the following:

The amount of memory used by AppleShare PC is:

- No resident DA or other options:	127,344 bytes
- DA resident with expanded memory option:	90,176 bytes
- DA resident (no graphics or memory options):	200,416 bytes
- DA resident and high-resolution graphics support:	215,776 bytes

DOS takes up approximately 40K. AppleShare PC with high-resolution graphics support for the EGA card and DOS will take up approximately 250K. This leaves 330K for applications. Major applications (word processors, spreadsheets, and so on) usually require 384K or 512K. No wonder the user runs out of memory.

In this kind of situation, do NOT install the DA into memory. Rather, activate the by running it as a program from DOS prior to executing the applications. The user can then make the connections to the printer before

executing applications.

The user does not have to execute the DA program each time the PC is turned on, if the ANET program is used and AppleShare PC is directed to connect to the LaserWriter or LaserWriters on startup. The ANET program is distributed with AppleShare PC.

IBM-to-LaserWriter IINT With MS Word: Slow Printing Problem

Revised: 3/4/90
Security: Everyone

IBM-to-LaserWriter IINT With MS Word: Slow Printing Problem

=====

This article last reviewed: 27 March 1989

Some users with DOS computers on an AppleTalk network using the AppleTalk card and running AppleShare PC have complained of slow printing to a LaserWriter IINT. If you print to a LaserWriter set for Diablo emulation across LocalTalk, keep the following facts in mind about Diablo emulation:

- 1) It is slow because the interpreter for Diablo code is written in PostScript and must be translated to PostScript within the LaserWriter before printing.
- 2) The printer may not be receiving an end-of-file or Control-D from Microsoft Word and is waiting for a time out before printing the page.

If the LaserWriter is set for Diablo emulation, try printing a multiple-page document to the LaserWriter. If the last page takes as much as three minutes to print, the LaserWriter is probably not receiving an end-of-page command.

If the LaserWriter is set for PostScript, use the Microsoft Word APPLASER driver (from the Microsoft Word printer driver disk).

A/UX: Development Tools (8/94)

=====
Article Created: 18 May 1989
Article Reviewed/Updated: 23 August 1994

TOPIC -----

This article lists tools Apple recommends for development for UNIX systems (not necessarily A/UX). This list was originally published for A/UX 1.0 but is still relevant for subsequent releases.

DISCUSSION -----

Under A/UX, the development tools can be summarized in the following categories:

1. Programming languages (compilers and interpreters)
 - cc (1) - The C compiler.
 - f77 (1) - The FORTRAN 77 compiler.
 - efl (1) - The Extended FORTRAN language.
 - cpp (1) - The C language preprocessor.
 - bs (1) - A compiler/interpreter for modest-sized programs.
 - sno (1) - The SNOBOL interpreter.
2. The Software Generation System (SGS) is a group of programs that recognizes a standard binary executable format known as Common Object File Format (COFF).
 - as (1) - Assembler.
 - dis (1) - Disassembler.
 - ADB (1) - Debugger.
 - sdb (1) - Symbolic debugger.
 - ar (1) - Library archiver.
 - ld (1) - Linkage Editor.
 - prof (1) - Profiler.
 - nm (1) - Display symbol table of common object file.
 - strip (1) - Strip symbol and line number from object files.

- ctrace (1) - C tracing utility.
- 3. The Source Code Control System, sccs(1), helps software developers control changes to source code and other text files.
- 4. A program maintenance utility, make (1), is a utility through which system developers define the dependencies among the components of a software system and specify the processing that should take place when one or more components change.
- 5. Terminal-independent I/O, curses (3X), lets programmers write programs that read from and write to terminals without concern for the specific type or brand of terminal. The curses routines can use either a database called "terminfo" or a database called "termcap" that contains a description of control sequences for various types of terminals.
- 6. Other program development tools include:
 - awk (1) - A pattern scanning and processing language.
 - yacc (1) - Yet another compiler-compiler, is a compiler-writing tool that uses a BNF-like specification to generate a language parser.
 - lex (1) - A program that uses a set of user-defined regular expression to generate a lexical analyzer that will analyze the tokens in the input stream.
 - lint (1) - A C program syntax checker.
 - cb (1) - A C program formatter.
- 7. Text processing tools
 - Text editors
 - ed (1) - A simple, interactive line editor.
 - ex (1) and vi (1) - a text-editing family composed of a line editor and full-screen editor.
 - sed (1) - A stream editor that transforms text based upon a command script usually stored in a file.
 - Documentaries Workbench (DWB)
 - nroff (1) - Format text for output to terminals and line printers.
 - troff (1) - Device-independent text formatter for phototypesetter.
 - psdit (1) - Convert troff intermediate format to PostScript format.
 - tbl (1) - Format text into tables.
 - pic (1) - Format simple line drawings.
 - eqn (1), neqn (1), checkeq (1) - Format and check command syntax of mathematical equations.
 - man (1) - Format text into UNIX-style manual entries.

- Other text-processing utilities.
- spell (1) - A spelling checker.
- grep (1) - A program that searches for strings or regular expressions within files.
- diff (1) - A program that reports the differences between two files.

These are all included free with the A/UX software package. Other companies may charge extra.

For a complete list of A/UX commands and detailed information, please refer to "A/UX Command References (A - L)", "A/UX Command Reference (M - Z)", and "A/UX Programmer's Reference".

Aside from the list above, third parties below have some development products available for A/UX. For more details, search the Tech Info Library under the company named.

Product name	Company name
=====	=====
ADA Compiler for A/UX	Alsys
Allegro CL, an extended common LISP	Franz Inc.
Data Access Language (DAL), formerly known as "CL/1.", a connectivity language	ITI

A/UX: Ethernet NIC Overflow Problems (8/94)

=====

Article Created: 29 March 1989
Article Reviewed/Updated: 24 August 1994

TOPIC -----

This article describes a known A/UX 1.0 networking problem that was reported to A/UX engineering. The problem is resolved in A/UX 3.0. This article is still useful in that it provides a good troubleshooting tip in the Analysis and Solution section.

DISCUSSION -----

Typical Network Configuration

The network that experienced this problem is configured as follows:
Ethernet network with A/UX systems, AT&T PCs, VAXs, and DEC terminals.

All Apple systems have Apple Ethernet cards with the new ROMs. The cable is a mixture of thick and thin. The network has connections to the outside world through gateways. Most of the time, the network is fine.

The Problem

On occasion, the user receives these error messages in the following order:

```
Transmitter frozen and resetting
ae_0 overflow
NIC reset failed
ae6_intr:receive overflow warning
```

After the error happens, the network has problems with RPC and NFS. "Show mount" says that the RPC Program did not register. If the user kills "initd" and restarts, everything works until the next time the error occurs.

On occasion, the user receives screens full of "mexpand returning 0" error

messages. Then, the transmitter resets, and the user discovers that "initd" isn't running anymore.

As a test, you can output from "netstat 1", "netstat -s", "netstat -m", and a login on an A/UX system on the network. Although the network doesn't appear to be too busy, there is a very high error rate.

There is also an IBM PC on another part of the network has been sending out broadcast storms (broadcasting all zeros) that cripple her network (A/UX systems and DEC terminals included). This is a recently detected problem that may have been going on earlier and may be contributing to the ae_0 overflow errors.

Analysis and Solution

The problem seems to involve the broadcast traffic that A/UX made and that was responded to by other machines.

At this point, the best thing to do is eliminate the broadcast traffic from and/or to the Macintosh A/UX machines by shutting down some of broadcasting daemons (like "rwhod") and/or to isolate the A/UX machines by subnetting them in a separate subnetwork.

For a temporary recovery from the situation, type the following commands to bring the network up again:

```
ifconfig ae0 down  
ifconfig ae0 up
```

LaserWriter and VAX: How To Fix An EEROM Problem (3/94)

Article Created: 29 March 1989
Article Updated/Reviewed: 18 March 1994

TOPIC -----

Some users, especially those with networks, have experienced peculiar situations wherein a LaserWriter (connected via AppleTalk to a Macintosh) works, while another LaserWriter (connected on a serial line to a VAX that spools its print jobs) won't. Quite often, an EEROM problem is involved. (The EEROM is where persistent parameters are stored.)

DISCUSSION -----

When a failure to print across the serial line occurs, the problem can be that the EEROM was left in a state that the VAX is unable to deal with. This can happen if the LaserWriter was serially connected to a non-Macintosh machine before being connected to the VAX. For example, there are a number of MS-DOS programs that leave a LaserWriter EEROM in a non-standard state.

Two common problem areas are improper setting of the "setdefaulttimeouts" persistent parameter in EEROM and the corruption of the EESCRATCH section of the EEROM. The EESCRATCH is the area of EEROM used to extend PostScript. It is also the area most likely to have been set up in a non-standard way.

Initializing (by running a print job) over AppleTalk is a good, simple way to correct the problem. When the LaserWriter is initialized over AppleTalk, the EEROM is set in a state that the VAX can work with. Thereafter, the VAX should be able to print the file.

The AppleTalk LaserWriter drivers can deal with this situation, because they communicate with the LaserWriter as it is printing. When the LaserWriter has an EEROM problem, the driver can set the EEROM up properly. Because the VAX is spooling the document, it cannot maintain this type of back and forth dialog with the LaserWriter.

ProDOS 8: How To Find Disk, Controller, and Block Information

Revised: 5/18/89
Security: Everyone

ProDOS 8: How To Find Disk, Controller, and Block Information

=====

This article last reviewed: 29 March 1989

This article describes how to find disk information, by making calls to significant memory locations.

Is the Card a Disk Controller?

Check memory locations \$Cs01, \$Cs03, \$Cs05 (s = slot number) for \$20, \$00, and \$03, respectively. If these values are found, then the card in the slot is a disk controller.

Apple Disk II Disk Controller and Disk Capacity?

Check memory location \$CsFF. If the value is \$00 or \$FF, assume that an Apple Disk II disk controller card is installed (\$00 is 16-sector, \$FF is 13-sector).

SmartPort Device and Number of Blocks?

If the device is not an Apple Disk II disk controller card, check memory location \$Cs07. If the value does not equal \$00, the device is not a SmartPort device, and the total number of blocks for the drive are stored at memory locations \$CsFC and \$CsFD in low-byte/high-byte order.

If the total number of blocks is 0, contact the card manufacturer for details on how to determine the number of blocks. (Note: We do not know of any disk controller that does not store the total number of blocks at memory locations \$CsFC and \$CsFD.)

If the value at memory location \$Cs07 is \$00, the drive is a SmartPort device. To find the number of blocks on the drive, you must make SmartPort status call \$03 (get DIB). This call is documented in the "Apple IIGS Firmware Reference Manual" on pages 114 through 125 with the most specific information starting on page 121.

A/UX: Calculating Packets per Second through Ethernet (8/94)

=====

Article Created: 29 March 1989
Article Reviewed/Updated: 23 August 1994

TOPIC -----

This article shows you how to calculate packets-per-second throughput across Ethernet.

DISCUSSION -----

To find the number of packets per second you can move through your Ethernet, do a quick and dirty test. Try "cp"ing or "cat"ing some files to and/or from an NFS file server. A rough test of "cp" (a 554181-byte file) with a 1K packet size took about 10 seconds (about 55K/sec).

roughly,	550,000 bytes		
	-----	=	550K in 10 seconds = 55K/sec
	1,000 bytes per K		

Some factors that might affect this number are network traffic, packet size, the load of the system, NMBUFS (buffers for networking), and so on.

Block-Mode Terminal Capability With VAX/VMS

Revised: 5/18/89
Security: Everyone

Block-Mode Terminal Capability With VAX/VMS

=====

This article last reviewed: 10 April 1989

This article describes why trying to do block-mode terminal emulation on a VAX running VMS is not a good idea. Essentially, it is a very complex, time-consuming process to convert software.

Having block-mode terminal capabilities on a VAX running VMS requires more than writing a terminal emulator. It also requires rewriting all of the programs that run on the VAX so that they support block-mode terminals. At the lowest level, VMS does support block-mode terminals. However, the lowest level only lets these features be implemented by an application. This requires the VMS application, itself, to implement all of the block-mode input and output routines that are usually accessible from the standard I/O routines on machines that run block-mode terminals.

Block-mode transfer is available from a specific model of DEC terminal in the VT100 family, the VT131. Currently, no terminal emulation package is available for the Macintosh that implements the block-mode features of the VT131. The alternative, then, is to write a terminal emulator with the necessary features.

Unfortunately, writing a terminal emulator that has block-mode features does not solve the problem on a VMS machine. The following quote from Digital's "Terminal and Printers Handbook" explains this:

"Digital currently supports the VT131 block mode under VAX/VMS version 3.0 and later versions. Support is at the operating system level, and this requires the use of third-party application programs to take full advantage of the VT131 features. This allows Digital software OEMs that use block mode terminals to use their software on Digital hardware with minimal modification. Digital has no plans to provide application software for the VT131 in other than VT102 (conversational) mode."

What this means is that although you could write a terminal emulator that has block-mode features, none of the standard VMS application software

would take advantage of those features. They would read the terminal in character-by-character (conversational) mode, anyway. Thus, to implement block mode, you would have to write the terminal emulator and rewrite every application on the system to support block mode. For example, the VMS editor would need to be completely rewritten.

The use of AppleTalk VMS does not solve this problem for the same reason that writing the terminal emulator will not. Standard VMS applications are still written for conversational mode. It is possible that performance might degrade in a situation where each character is transmitted in its own AppleTalk packet with the echoed character also returned in its own packet.

Security: Everyone

Sony MultiScan: Troubleshooting Ghosts

=====
Article Created: 10 April 1989
Article Last Reviewed: 6 July 1992
Article Last Updated:

TOPIC -----

This article describes troubleshooting techniques for clearing video "ghosts" from a Sony Video Graphic MultiScan Projector Model # VPH-1030Q1 attached to a Macintosh II, RGB 8-bit AppleColor Monitor.

DISCUSSION -----

Usually a ghosting image appears because of transmission problems. Such problems are usually because of the cables. Causes include:

- The cable not having enough grounds connected
- A poor ground connection
- Poor shielding on the cable
- Cable length extended too far (depending on the cable and signal). In this case, the cable should be no longer than 50 feet, if at all possible.

First, check the cables. If that doesn't solve the problem, consider these three possibilities:

- All of the video grounds from the Macintosh II video card should be connected to the grounds on the projector.
- The best type of cable is RG-59 75-ohm cabling.
- The Sony 1031Q supports a multiscan ability of up to 36 KHz for horizontal. This is more than enough for our 34 KHz horizontal signal.

The bandwidth will cause a blurring if it is much less than 20 MHz, and would be best at 30 MHz.

There are ten open ground pins for connection on the RGB2 connector. Four of these should be used for pins 1, 4, 6, and 11 of the Macintosh II card. Leave pin 9 of 1031 RGB2 connector open for analog video input.

The pin connection should be as follows:

Macintosh II video card	1031Q RGB2 connector
-----	-----
1 (ground) -----	15
2 (red) -----	6
4 (ground) -----	16
5 (green & composite sync) -----	5
6 (ground) -----	17
9 (blue) -----	4
11 (ground) -----	18

Apple II: Starting Over Bridges

Revised: 5/18/89
Security: Everyone

Apple II: Starting Over Bridges

=====

This article last reviewed: 10 April 1989

When an internet has each side of the InterBridge assigned a different zone name (common practice when using the InterBridge) In this type of internet, the Apple IIe and the Apple IIGS cannot boot across an InterBridge.

However, when both sides of the InterBridge have the same zone name on a one-zone internet, the Apple II systems can start across the InterBridge. This difference occurs, because AppleTalk uses the Name Binding Protocol to understand the network design. (AppleTalk is more concerned with names than it is with numbers.) With both sides of the InterBridge having the same zone name, AppleTalk believes it is dealing with one network (one zone).

This method of name assignment has one disadvantage. All network traffic is passed across the InterBridge, thus defeating the usual reason for installing the bridge--the logical separation of network traffic.

Note: Routers and bridges are different devices. They do perform similar functions, but the router is a higher-level device than the bridge.

GS/OS 4.0 and Checkmate MemorySaver

=====

This article last reviewed: 10 April 1989

Some users have reported problems installing GS/OS on the Checkmate MemorySaver using the Installer and the Control Panel to set the start-up slot. In fact, using the Installer to put GS/OS on the MemorySaver may be the cause of the difficulties. Rather, follow these two steps:

- 1) Use the Installer to create a boot disk configured the same as the desired MemorySaver configuration.
- 2) Copy the contents of the configured boot disk to the MemorySaver.

Checkmate Technologies provided the following suggestions:

- Do not create a RAM disk in the Control Panel.
- Check MemorySaver partitions; you need one large enough to accommodate your configuration of GS/OS.
- Use a copy program like "System Utilities", instead of the Installer or the Finder "drag" copy technique.

Sharing CD-ROMs With PCs, VMS, and UNIX

Revised: 6/28/89
Security: Everyone

Sharing CD-ROMs With PCs, VMS, and UNIX

=====

This article last reviewed: 26 June 1989

This article discusses CD-ROM compatibility with different operating systems. The issue is very similar to the use of data files in differing operating systems. That is, to work properly, the operating system needs to understand the structure provided.

Operating Systems

The High Sierra disk format was worked out by a diverse group of computer industry companies. The format was designed to have the least impact on largest number of operating environments. However, simply because the standard exists, does not mean all environments can mount High Sierra CD-ROMs.

Each operating system publisher needs to adapt its environment so that its OS understands the High Sierra structure. Apple did this with a Startup Document which is placed in the System Folder.

The two companies, Online Computer Library and SilverPlatter currently have MS-DOS versions of their search engines in production.

File Structure

Once the operating system understands the disk structure, the next issue is understanding the file structure. If an ASCII text file is written to a High Sierra format CD-ROM, any operating system that understands High Sierra can read the text file directly.

However, when dealing with a large collection of information, an ASCII text file is not the most efficient file structure for quickly retrieving specific information. Most companies providing information on CD-ROM format, prefer their own file format, one with an indexing method for subject matter. The software for reading a particular file format-indexing method has become known as the "search engine".

CD-ROMs in UNIX and VMS

There are two issues involved with reading these particular CD-ROMs in UNIX and VMS. The first issue concerns the adoption of the operating system to allow the mounting of a High Sierra volume. To our knowledge, DEC has not implemented High Sierra drivers within VMS. There are too many versions of UNIX in the world for blanket statements to be valid.

The next issue concerns individual companies creating the retrieval software. Because access to the information provided by certain companies requires the company to write the retrieval software, deciding if it is reasonable to provide the software for VMS and UNIX is a decision left to the companies themselves.

One source that Apple is aware of concerning the latest information in CD-ROM industry follow is: Meckler Corp's "CD-ROM Librarian".

For more details, search the Tech Info Library under "Meckler", "Online Computer Library", and "SilverPlatter".

Macintosh: Fortune 8025 Connectivity

=====

Article Created: 10 April 1989
Article Last Reviewed: 10 August 1992
Article Last Updated: 10 August 1992

TOPIC -----

Do you know how I can connect a Macintosh to Fortune 8025? And do you have any information about Fortune terminal emulation?

DISCUSSION -----

We assume you mean the Fortune computer that was marketed 5 to 7 years ago, a UNIX computer that used UNIX System 7. Any terminal emulation that can be defined in "termcap" can be used with this system. The VT100 emulation provided in many Macintosh telecommunications applications would work.

Here are three Macintosh-to-Fortune 8025 Communication solutions.

- NCSA Telnet is probably the best solution. Telnet is a solid, feature-rich, public-domain, VT100 emulator. It requires an Ethernet connection and a Kinetics FastPath, if you are connecting via PhoneNET or LocalTalk. Telnet supports UNIX FTP.
- Kermit is a file-transfer protocol. The public-domain Kermit package for Macintosh also provides terminal emulation.
- MacTerminal or equivalent creates an asynchronous connection with ASCII text transfer only.

For more information, search for NCSA Telnet, Kermit, or MacTerminal.

AppleShare PC and LaserWriter Printer Emulations

Revised: 12/6/89
Security: Everyone

AppleShare PC and LaserWriter Printer Emulations

=====

This article last reviewed: 10 April 1989

AppleShare PC allows the capture and redirection of printer output from a PC application to the attached and selected LocalTalk printer (LaserWriters and so on).

If you have a LaserWriter and want to output to a "normal" PC printer, select the printer at "LPT2:" (or other valid LPTx: address) to be a networked LaserWriter that emulates an Epson LQ2500 or preferred device. If you have a LaserWriter and want to send output to a PostScript printer, select the printer at "LPT3:" (or other valid LPTx: address) to be a networked LaserWriter that emulates a PostScript printer.

You can select the SAME networked LaserWriter to be both the Epson LQ2500 and the PostScript printer via two different line printer (LPTx:) logical addresses. Using the LPTx ports in this manner is a standard part of testing. There are no special techniques for accomplishing the described procedure. The most difficult part of the process is remembering which LPTx belongs with which emulator.

A/UX: Advantages of dump.bsd (8/94)

Revised: 8/23/94
Security: Everyone

A/UX: Advantages of "dump.bsd" (8/94)

Article Created: 3 April 1989
Article Reviewed/Updated: 22 August 1994

TOPIC -----

What are the advantages of using dump.bsd?

DISCUSSION -----

As described in the Local System Administration guide section on Backing Up Your System, the programs "dump.bsd" and "restore" can be used for backup.

The dump.bsd command is used for partial or full file system backups. The restore program is the companion utility of dump.bsd. It retrieves files and directories from a backup medium created with dump.bsd.

The ADVANTAGES of using dump.bsd and restore include the following:

- dump.bsd is generally faster than tar or cpio.
- They allow you to back up only those files modified or created after a certain date.
- The restore command can extract files by their inode numbers.
- A variation of the dump.bsd command, rdump, allows you to back up files over a network.
- You cannot inadvertently backup a file system located on a remote computer.

The DISADVANTAGES of using dump.bsd and restore are as follows:

- They operate only on file systems. As distributed, A/UX has only one file system, so this is not initially a drawback. However, if you add one or more file system, your use of these backup utilities becomes more complicated because you have to backup the file systems individually.

- You must be sure the system's date and time are always correct, or you are likely to lose files when restoring from an incremental backup.
- Backups made with dump.bsd cannot usually be transferred to other systems.

A/UX: Some Error Messages Explained (8/94)

Article Created: 3 April 1989
Article Reviewed/Updated: 22 August 1994

TOPIC -----

This article describes the meanings of four A/UX error messages:

- "procdup - can't get 2 pages for udot"
- "SCSI timeout"
- "SCSI reset"
- "ku_fastsend: if_output failed:"

DISCUSSION -----

"procdup - can't get 2 pages for udot"

This message indicates that a kernel memory allocation request failed. It seems that there is not enough memory, and/or there are too many processes running on the particular A/UX system. A suggestion is to add more memory or run fewer processes. With such a message, you should also do the following:

- 1) Run the "kconfig -av", "pstat -m", and "netstat -m" commands.
- 2) Examine the output of these commands.
- 3) Adjust the system parameters from the "kconfig", if necessary.

"SCSI timeout"

This indicates that the SCSI was running into a situation (like doing a huge file transfer) that caused the device driver to issue a SCSI I/O request to a device. The device, has in turn, timed out before it can process the request from the driver.

"SCSI reset"

This was sent from the SCSI manager to the driver simply to clear out any timeout errors. This symptom had been reported in the A/UX Bug Report Database. There is a lot of improvement and many fixes to the SCSI driver since A/UX 1.1.

"ku_fastsend: if_output failed:"

This indicates a failure occurred on an interface output routine when the driver or the controller tried to send data to Ethernet. The "error=70" indicates "Network is down". This might be caused by the previous error messages.

A/UX: Shell Argument Limit

Article Created: 3 April 1989

Article Change History

08/27/92 - REVIEWED
o For technical accuracy.

TOPIC -----

Some users have tried unsuccessfully to pass large command-line arguments.

DISCUSSION -----

The problem with the large command line is a shell problem; the shell can't work with the large command line parameters. Passing a large command line to "awk" or to other utilities creates problems. For example, If you try to "echo" a lot of characters (as shown below), it won't work.

```
1  echo '  
2  XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX  
3  XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX  
4  :::  
5  ' a lot more X's '  
6  :::  
24 XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX  
25 XXXXXXXXXXXXXXXXXXXXXXXX  
26 '
```

The Korn shell has the same problem, only it allows a much larger number of characters. The Korn shell doesn't dump a core, while "csh" and "sh" do. It seems that the A/UX shells (Bourne, Csh, or Korn) have limitations on the size of their arguments.

The same echo command is successful on a BSD UNIX system.

=====

Apple IIfc Plus Memory Card: Using with Apple IIfc Plus (2/97)

Article Created: 18 May 1989
Article Reviewed/Updated: 12 February 1997

TOPIC -----

This article discusses using the Apple IIfc Memory card in the Apple IIfc Plus.

DISCUSSION -----

The Apple IIfc Plus manual, page 110, states, (The Apple IIfc Memory Expansion Card is not designed to be used with the Apple IIfc Plus. Ask your authorized Apple dealer to recommend a compatible card.)

The design of the Apple IIfc Plus is such as to render the Apple Memory Expansion Card unstable, because of timing problems associated with the gate array.

Use of the expansion card in an Apple IIfc+ supported by Apple.

Macintosh-To-Sun Connectivity (10/95)

=====

Article Created: 11 April 1989
Article Reviewed/Updated: 12 October 1995

TOPIC -----

This article describes a number of different solutions for connecting Macintosh systems to Sun workstations. Many of them are applicable to other UNIX systems, as well.

DISCUSSION -----

In terms of connections to UNIX services, like Telnet, NFS, and FTP; look at products like NCSA Telnet, and the products from Cayman, the makers of the Gator Box.

NCSA Telnet is a Macintosh telecommunications program written by the National Center for Supercomputing Applications at the University of Illinois, Champaign-Urbana. It provides a VT100 connection to UNIX systems that have Telnet services. NCSA Telnet also provides FTP (File Transfer Protocol) uploading and downloading and Tektronix 4010 terminal emulation. The most recent version of NCSA Telnet (version 2.2) supports direct connections to an Ethernet via an EtherTalk card (or the EtherPort cards from Kinetics) and connections over LocalTalk/PhoneNET through an AppleTalk-to-TCP/IP gateway, like the FastPath from Kinetics.

Cayman Corporation has products that let you bring an NFS server's volume up as volumes on your Macintosh desktop as if they were standard Macintosh volumes. This is achieved through the use of their Gator Box and their software. The Gator Box is similar to the Kinetics FastPath, in that it provides an AppleTalk-to-TCP/IP gateway from a LocalTalk physical media to an Ethernet.

The GatorBox is a LocalTalk-to-Ethernet router with the additional functionality of converting AppleShare requests and responses to NFS requests and responses. This lets a network of Macintoshes view Suns as if they were AppleShare file servers with no special software required for either the Macintoshes or the Suns.

CAP (Columbia AppleTalk Package) is a public domain product from Columbia University that turns UNIX systems into AppleShare servers that can be accessed through the Chooser. It also provides various print services for those UNIX systems.

MacKermit is a public domain, serial-based telecommunications program providing VT100 emulation and uploading and downloading via the Kermit file transfer protocols. Most UNIX systems also have Kermit support, and this program provides good asynchronous access and file transfer capabilities to these systems.

Ungerman-Bass Corporation has announced Telnet and FTP programs for the Macintosh, based upon our announced, but not yet released, MacTCP driver.

uShare is a product from Information Presentation Technologies. uShare is comparable to PacerShare or AlisaShare, but for UNIX -- it is software that runs as a process under UNIX and permits the Sun systems that run it to act as AppleShare file servers. A Kinetics FastPath would still be needed to bridge LocalTalk and Ethernet.

Our UNIX product, A/UX, provides full access to Sun workstations on the same network. This access includes NFS, Telnet, FTP, Yellow Pages, and other network programs, like "rlogin" and "rcp".

Currently, there are no products that translate data files other than raw text files between Suns and Macintoshes. Many of the terminal and file transfer programs listed above do this properly.

Macintosh II: Can't Use 16 Colors Setting Desktop Pattern

=====

This article last reviewed: 11 April 1989

Some Macintosh II users with 8-bit or 4-bit video cards and color monitor, running System software 6.0.2 or 6.0.3 have run into a minor problem when using the Control panel. Results are different depending on whether you set video for 256 colors or 16.

For example, select the Control Panel, and then set the card for 256 colors. Now select General and use the arrows above the sample patterns to move through the predefined options. Create a colored desktop pattern and change your desktop pattern to the new colored pattern. Now select any one of the other Control Panel icons (like Mouse, Keyboard, Monitors, Color, or other), and watch the desktop pattern. If you followed every step, then you should see no unexpected changes while doing the above steps.

Now, set up your video for 16 colors and do the same steps. You should notice that the desktop colors change as you step through the various, predefined, desktop patterns. In addition, they change when you select other Control Panel devices.

The reason 256-color mode works properly and 16-color does not is unusual but not an anomaly. The General CDEV uses the standard system "CLUT" (color look-up table) to define the variety of colors and patterns it stores as default options. The system color-look-up table contains 256 separate entries or colors. When the system is set to the 16-color mode, only 16 of the 256 colors are accessible at a given time, and the system defines 16 colors as the 16-displayable or default colors.

The General CDEV adjusts the 16 default colors to the colors used by its patterns or the patterns created by the end user, as they are selected. This adjustment of the 16 default colors remains in affect only as long as the General CDEV is active. As soon as another CDEV is chosen or the Control Panel is closed, the 16 default colors revert back to those set as default by the system, which causes the desktop colors to change.

Macintosh: How To Transfer CP/M Text Files

=====
Article Created: 18 May 1989
Article Last Reviewed: 26 May 1992
Article Last Updated: 26 May 1992

TOPIC -----

There are two ways to move documents from a CP/M machine to a Macintosh. The first is to put the documents in text-only format and send them through the serial port. The second is to use a "disk translator" program.

DISCUSSION -----

- Serial Port Transfer

To send documents from a CP/M system to a Macintosh, first save the files from the application that originated them as text-only documents on the CP/M system. Next, transfer the files through the serial port to a Macintosh using a terminal emulator. The computers can be connected via modem or direct cables. Transferred text files are easily opened by most Macintosh applications.

- Disk Translator Programs

There are several products on the market for the IBM and for CP/M machines that read and write different disk formats. One such program is Media Master for the IBM. This program lets you insert a non-IBM-format disk, like Kaypro, SuperBrain, Osborne, or other, into the IBM and save it to IBM format. Once the information is in IBM format, you can use Apple File Exchange, Apple PC Exchange or any other DOS-to-Mac transfer utility to read the information on the Macintosh. The Apple FDHD SuperDrive allows direct transfer of the data from an IBM 3.5-inch disk.

A/UX: Bourne Shell: "ulimit" Security Problem

=====

Article Created: 6 April 1989

Article Change History

08/27/92 - REVIEWED
 o For technical accuracy.
08/27/92 - UPDATED
 o To include A/UX 3.0 Information.

TOPIC -----

Here's a security problem in A/UX 1.0 and 1.1. It does not apply to A/UX 3.0.

```
$ulimit 0
$passwd          # this command means do the normal passwd routines
```

DISCUSSION -----

After this, the "/etc/passwd" file is truncated to 0 length. This works both as "su" and as a normal user. This problem has been verified in the Bourne Shell "ulimit" built-in function.

If anyone wants to verify it, login as "root". Otherwise, you can't get back your root access.

=====

Article Created: 18 May 1989
Article Reviewed/Updated: 26 July 1993

TOPIC -----

DCA's (formerly Avatar) "MDPIC" Puts Graphics In "troff" Documents

DISCUSSION -----

A program called "MDPIC" from DCA (formerly Avatar) interprets Macintosh text and graphics formats and converts them into "pic" and "troff" format. The "pic" is the generalized graphical front end to "troff" through which users can include graphics in "troff" documents. "pic" works in much the same way as "tbl" and "eqn".

MDPIC is application-independent; with it, you create "pic" and "troff" graphics using MacDraw, Excel, MacProject, MacDraft, Cricket Draw, MacWrite, and, in fact, almost any Macintosh application (according to their advertisement). To locate a vendor's address and phone numbers, use vendor name as a search string.

Apple IIC Plus: External Pinouts (6/94)

Article Created: 24 May 1989
Article Reviewed/Updated: 24 June 1994

TOPIC -----

This article gives the pinouts for the following ports for Apple IIC Plus:

- DB-9 Mouse or Joystick Port
- DB-19 Disk Drive Port
- DB-15 Video Expansion Connector
- MiniDin-8 Modem Port (with startup characteristics)
- MiniDin-8 Printer Port (with startup characteristics)

DISCUSSION -----

DB-9 Mouse or Joystick Port

-
- 1- MOUSEID* Mouse identifier: when active, disables NE556 hand controller timer.
 - 2- +5V total current drain from this pin must not exceed 100 mA.
 - 3- GND System Ground.
 - 4- XDIR Mouse X-direction indicator.
 - 5- XMOVE Mouse x-movement interrupt.
 - 6- N.C. Not connected.
 - 7- MSW* Mouse button.
 - 8- YDIR Mouse Y-direction indicator.
 - 9- YMOVE Mouse Y-movement interrupt.
-
- 1- GAMESW1 Switch input 1 (sometimes called paddle button 1).
 - 2- +5V total current drain from this pin must not exceed 100mA.
 - 3- GND System ground.
 - 4- Not Used for hand controller.
 - 5- PDL0 hand controller input. Must be connected to a 150K ohm variable

- resistor connected to +5V.
- 6- N.C. Not connected.
- 7- GAMESW0 Switch input 0 (sometimes called paddle button 0).
- 8- PDL1 hand controller input; must be connected to a 150K ohm variable resistor connected to +5V.
- 9- Not used with hand controller.

DB-19 Disk Drive Port

-
- 1,2,3- Ground.
 - 4- 3.5DISK 3.5 or 5.25-inch drive select.
 - 5- -12V -12 volt supply.
 - 6- +5V +5 volt supply.
 - 7- +12V +12 volt supply.
 - 8- +12V +12 volt supply.
 - 9- DR2 Drive 2 Select.
 - 10- WRPTOTECT Write protect input.
 - 11- PHASE0 Motor Phase 0 output.
 - 12- PHASE1 Motor Phase 1 output.
 - 13- PHASE2 Motor Phase 2 output.
 - 14- PHASE3 Motor Phase 3 output.
 - 15- WREQ Write request.
 - 16- HDSEL Head Select.
 - 17- DR1 Drive 1 select.
 - 18- RDDATA Read data input.
 - 19- WDATA Write data output.

Note: Power connectors on this port are for use by the disk drive only.

DB-15 Video Expansion Connector

-
- 1- TEXT Video text signal from TMG; set to inverse of GR, except in double high-resolution mode.
 - 2- 14M 14M master timing signal from the system oscillator.
 - 3- SYNC* Displays horizontal and vertical synchronization signal from IOU pin 39.
 - 4- SEGB Displays vertical counter bit from IOU pin 4; in text mode, indicates second low-order vertical counter; in graphics mode, indicates low-resolution.
 - 5- 1VSOUND One-volt sound signal from pin 5 of the audio hybrid circuit (AUD).
 - 6- LDPS* Video shift-register load enable from pin 12 of TMG.
 - 7- WNDW* Active area display blanking; includes both horizontal and vertical blanking.
 - 8- +12V Regulated +12 volts DC; can drive 300mA.
 - 9- PRAS* RAM row-address strobe from TMG pin 19.
 - 10- GR Graphics mode enable from IOU pin 2.
 - 11- SEROUT* Serialized character generator output from pin 1 of the 74LS166 shift register.
 - 12- NTSC Composite NTSC video signal from VID hybrid chip.
 - 13- GND Ground reference and supply.
 - 14- VIDD7 From 74LS374 video latch; causes half-dot shift high.
 - 15- CREF Color reference signal from TMG pin 3; 3.58 MHz.

Note: The signals at the DB-15 on the Apple IIC are not the same as those at the DB-15 end of the Apple III, Apple II GS, and Macintosh II. Do not attempt to plug a cable intended for one into the other.

Several of these signals, such as the 14 MHz, must be buffered within about 4 inches of the back panel connector--preferably inside a container directly connected to the back panel.

MiniDin-8 Modem Port

- 1- DTR Data Terminal Ready (output).
- 2- DSR Data Set Ready (input).
- 3- TD Transmit Data (output).
- 4,6,8- Ground.
- 5- RD Read Data (input).
- 7- N.C. Not connected.

Start-up Characteristics

300 baud
8 data bits
No parity
1 stop bit
No screen echo
No Line Feed after Carriage Return (no LF after CR)
No Carriage Returns in output stream
Command Char= Control-A

MiniDin-8 Printer Port

- 1- DTR Data Terminal Ready (output).
- 2- DSR Data Set Ready (input).
- 3- TD Transmit Data (output).
- 4,6,8- Ground.
- 5- RD Read Data (input).
- 7- N.C. Not connected.

Start-up Characteristics

9600 baud
8 data bits
No parity
2 stop bits
80-column line
No screen echo
Line Feed after Carriage Return
Command Char= Control-I

The MiniDin-8 pin configuration is this: As you look at the back of the machine, pin 1 being lower-right, pin 3 middle-right, pin 6 upper-right.

Farallon PhoneNET: Troubleshooting Information

=====

This article last reviewed: 11 April 1989

The typical reason for strange behavior in PhoneNET networks is having drops from a backbone that contain resistors at their ends. A PhoneNET network should have only two terminating resistors: one at each end of the network. If a StarController is being used, there should be one resistor at the end of each drop from the StarController.

Each added resistor pulls down the voltage level across the whole network. This will cause uneven performance as the signal is degraded to below the response level of the nodes and/or the serial ports. The signal may be acceptable near the source but, depending on the configuration of the network, the signal will probably be pulled lower than can be registered by a destination node or serial port as it moves away from the source.

The nodes may be receiving signals at the lower limit of their sensitivity (something under 5 volts). For example: The voltage level is normally 5 volts when high. If added resistors increase the impedance of the network without any added current to draw from, the voltage level may be around 4 volts, depending on how many extra resistors are added, and how far from the source the receiving node is.

Now, assume that the nodes are specified to work with 4.5 to 5.5 volts, but are actually sensitive to signals as low as 4 volts. (Most will be, but some may be sensitive to only 4.5 volts.) These are perfectly good nodes on a properly configured network. Because your network might have signals at 4.2 volts in some places and 4.6 volts in others, some nodes, sensitive to 4.5-volt levels, would not receive the signals in some spots and will in others.

Double-Density Versus High-Density Disks

Revised: 8/22/91
Security: Everyone

Double-Density Versus High-Density Disks

Article Created: 25 May 89
Article Last Reviewed: 22 August 1991
Article Last Updated: 22 August 1991

TOPIC -----

This article gives the specifications for the 800K floppy disks and the 1.4MB floppy disks. It also describes why you should not drill a hole in a double-density disk and format it as a high-density disk.

DISCUSSION -----

The table below compares the formatted capacity of the different media:

	800K Disk	1.4MB Disk
	1600 sectors	2880 sectors
	-----	-----
Bytes/Sector	512	512
Sectors/Track	8-12	18
Tracks/Side	80	80
Bytes/Side	409,600	737,280
Bytes/Disk	819,200	1,474,560

The Apple SuperDrive (formerly Apple FDHD) can read and write to any of the major 3.5-inch disk formats, including Macintosh (GCR 400K, 800K, and MFM 1.44MB), Apple II (800K), and MS-DOS and OS/2 (MFM 720 and 1.44MB). GCR stands for "Group Code Recording" and MFM stands for "Modified Frequency Modulation".

When the SuperDrive writes 400K/800K disks in GCR mode, the motor speed is variable, and the disk surface is divided into five zones to allow a constant recording density as the head moves from the outer edge to the center. When using high-density media, data is written in MFM mode, and the drive speed is constant for each track.

The table that follows compares the speed of the different disk structures:

Tracks	800K Disk	1.4MB Disk
-----	-----	-----
00-15	394/12	300/18
16-31	429/11	300/18
32-47	472/10	300/18
48-63	525/9	300/18
64-79	590/8	300/18

Revolutions Per Minute/Sectors Per Track

GCR and MFM only affect how the data is written to the disk. GCR and MFM do not care how the tracks and sectors are laid out on the disk. They also have no effect on the directory structure. GCR and MFM deal with how the bits are recorded on the surface of the media.

The MFM Method

MFM was originally recommended by Shugart Associates for double-density, floppy drives and was used in a small number of systems. IBM was the first major vendor to use MFM, and now Apple also provides MFM support for the Apple SuperDrive. MFM uses a transition pulse to write data to drive media. There are two locations for the transition pulse: the data boundary or the cell boundary. A transition occurs at a cell boundary only when two zero bits occur next to each other. This encoding method guarantees that no more than two-bit cells can occur without a transition and is, thus, self-clocking.

The GCR Method

GCR is a method that Apple has used to record information since the Apple II Disk Controller. Each group of four bits is translated into a 5-bit code (the Run-Length code). A translation table is used to find this 5-bit code. This 5-bit code seems to increase data bits by 20%. However, the 5-bit codes never contain more than two consecutive zeros, and GCR writes the data in NRZI format. When a 1 occurs in the data stream, a transition occurs on the data boundary. Thus, GCR is guaranteed to be self-clocking. You also save the cell boundary transitions required for MFM. Thus, GCR is more efficient than MFM and is widely used in high-density disks and tape recordings. The disadvantage of GCR is the relatively high complexity of the encoding and decoding logic.

High-Density vs Double-Density Disks

High-density disks are physically different and tested to a different specification than double-density disks. In this case, high-density disks are of higher quality than double-density disks. The high-density disks have a special, thin, recording surface that allows the higher data rates used in MFM. The 800K or 400K disk may not be sensitive enough to properly pick up and align the magnetic particles when the SuperDrive writes in MFM. This could cause corruption of the stored data and may result in errors. Thus, it is unreliable, unsupported, and not suggested.

System Software:Installation On a One-Floppy-Drive System (2/95)

Article Created: 25 May 1989
Article Reviewed/Updated: 22 February 1995

TOPIC -----

This article explains a workaround for system software installation on a one-floppy-drive system.

DISCUSSION -----

If your Macintosh has only one floppy disk drive and no hard disk drive (for example: a Macintosh II, Macintosh IIfx, or Macintosh SE/30 with no hard disk), you can still install system software 6.0.3 onto a bootable floppy disk.

Such a System Software upgrade, even on a Macintosh IIfx with an Apple SuperDrive (formerly Apple FDHD), takes 402 disk insertions (or disk swaps).

Rather than numerous disk insertions/swaps, a simpler procedure may be to use a RAM-disk program. On a system with 2 or more megabytes (MB) of RAM, you can create a RAM disk of 800K to 1500K, and then copy the Installer and associated files to it. The Finder on the RAM-disk could be Option-clicked to make it become the start-up disk. After restarting with the RAM disk as your startup disk, you can run the installation as though a two-floppy system were being used.

Article Change History:

22 Feb 1995 - Reviewed for technical accuracy and added the commonly used term "disk swap" to enhance searching capabilities.

A/UX: How to Start from an External Disk (8/94)

Article Created: 4 April 1989
Article Reviewed/Updated: 23 August 1994

TOPIC -----

This article discusses the following error message:

```
Disk c0d0s0
Error: Cannot select SCSI device generic disk c0d0s0
Fatal Error: Logical block 0, physical block 1768387954
chroot failed
```

```
startup#
```

DISCUSSION -----

This error appears when the startup shell looks to see which disk you want it to automatically launch and encounters a problem. It is most likely because the A/UX startup device is different than the device on which the A/UX Startup application is installed.

As shipped, A/UX Startup is configured to start the A/UX kernel from the same disk that contains A/UX Startup. You can change this to have A/UX Startup start the A/UX kernel from another device, which must be identified as a SCSI device with an ID from SCSI ID 0 through 6. The A/UX kernel must be in the root file system of the disk you select as the boot device.

To change the A/UX startup device to be different than the device on which the application A/UX Startup resides, follow these steps:

- 1) Start the A/UX Startup application.
- 2) Cancel the A/UX Startup application: press CMD-period.
- 3) Choose the General menu item from Preferences in the menu bar.

4) Identify the SCSI ID of the hard disk that contains the root file system and kernel.

Initially, the Root Directory box contains the (default)/ parameter, which is the disk on which A/UX Startup resides. Change this parameter only when the root file system is on a different disk than A/UX Startup.

5) Change the (default)/ parameter in the Root Directory Box.

Enter the SCSI ID number of the device you want to use as the A/UX startup device; use the following format where ID is the SCSI ID number:

(ID,0,0)/

6) Click the OK box.

7) Start A/UX by choosing Boot from the Execute menu.

A/UX: The Macintosh Toolbox, "rlogin", and Xindows (8/94)

Article Created: 25 May 1989
Article Reviewed/Updated: 23 August 1994

TOPIC -----

This article discusses the relationship of the A/UX Toolbox to "rlogin", and XWindows.

DISCUSSION -----

The basis for the statements in this article is that the current implementation of A/UX Toolbox does not let any device other than the local console device ("/dev/console") access the Macintosh Toolbox ROM functions.

- 1) You cannot launch a Toolbox application after an "rlogin" to the other Macintosh A/UX. If you launch it, you will get an error message similar to the one below:

```
Can't open video device
/dev/console: Permission denied
Fatal error in Toolbox
```

This happens only if you rlogin as somebody different than whoever is logged into the console.

- 2) From your local A/UX Macintosh, you can run the Toolbox "term" program, then "rlogin" to another A/UX Macintosh. After you are in the remote Macintosh A/UX system, no more Toolbox applications can be executed. It will give you the same error message as above, if you execute it.
- 3) You cannot run a Macintosh Toolbox application under an X11 window. The reason is that they are two different window systems, and both use the same console device. They don't know each other and don't know how to share the resource. If you run a Toolbox application under X11 windows, you will get an unpredictable result, like getting the console mixed up and/or the system hanging.

A/UX: Why You Can't Set I/O Buffer Size (8/94)

=====

Article Created: 4 April 1989
Article Reviewed/Updated: 23 August 1994

TOPIC -----

Some users have wanted to increase the serial input/output buffer size to improve system performance.

DISCUSSION -----

You probably won't be able to do this in a direct fashion. The reason is that a linked list of data structures in the kernel controls A/UX serial input and output. These structures include:

- "clist" (the head of a linked-list queue of characters)
- "cblock" (a character-block structure)
- "ccblock" (a character-control block for interrupt-level control).

Some of the data structure sizes were constant when the A/UX kernel was built. These include "CLSIZE" (26, size of "clist" block) defined in the "clist" structure and the "TTYHOG" (256, maximum number of input characters buffer). As a result, you cannot change these numbers, unless you have source to recompile the kernel. Likewise, it is doubtful that the programming can change these constants.

However, there is a kernel-tunable parameter called "NCLIST" (number of system "clists"). You can raise this number with the "kconfig" command. This might speed up the input/output processing.

MacWorkStation: The X003 and X004 Exec Modules

=====

This article last reviewed: 12 April 1989

This article describes the difference between the X003 Invoke Exec Module and the X004 Call Exec Module.

The X003 Invoke Exec Module command actually runs the external procedure. You call this module after you have loaded the procedure and want it to execute for the first time to initialize its structures and perform its function.

The X004 Call Exec Module command passes data to an external procedure that has already been run by the X003 command. The data is passed in the "msgData" field of the TRMsg record that is sent to your external field.

MacWorkStation: MARK Parity Workaround

=====

This article last reviewed: 12 April 1989

A developer of a TCP/IP network contributed the following tip.
MacWorkStation does support MARK parity, even though it is used on some
mainframes. To work around this, try defining settings as follows:

Mark parity, 7 data bits, 1 stop bit

as:

No parity, 7 data bits, 2 stop bits

This kludge seems to be working, but MacWorkStation should support all
parity settings, including EVEN, ODD, NONE, SPACE, and MARK. Note that NONE
can mean no parity bit (NONE) or a zero bit (SPACE), depending on the
vendor.

LocalTalk: 32-Device Limit Is a Recommendation (8/95)

=====

Article Created: 12 April 1989
Article Reviewed/Updated: 14 August 1995

TOPIC -----

This article describes the 32-device limit recommended for LocalTalk cabled networks.

DISCUSSION -----

The 32-node limit for LocalTalk is a recommendation. It is specific to AppleTalk networks using LocalTalk cabling scheme. The considerations for this limit is the average traffic generated by these nodes and the physical transmission limitations of LocalTalk, so the 32-node limit is more of a performance limit.

Having more than 32 nodes can have an impact on network performance. Since there are 254 possible node addresses on a LocalTalk network, using all possible node IDs will reduce network performance due to increased traffic.

The node addresses are divided up this way:

1 - 127 are user node IDs
128 - 254 are server node IDs
0 and 255 these two node IDs are reserved

From a traffic standpoint, only active nodes have an effect on performance. In addition, both active and non-active workstations affect the electrical characteristics of the network, because the LocalTalk connector box (transformer isolation) puts a load on the network, regardless of whether the workstation is on.

The document, "Inside AppleTalk", gives detailed technical information about AppleTalk. It is available to members of the Apple Programmers and Developers Association (APDA). To get an APDA membership application and to order this publication, write or call APDA. To find APDA's address,

search the Tech Info Library under "APDA".

Apple IIGS: Tabbing In Applesoft BASIC

Revised: 5/25/89
Security: Everyone

Apple IIGS: Tabbing In Applesoft BASIC

=====

This article last reviewed: 21 April 1989

An Applesoft "PRINT TAB" statement, such as:

```
PRINT TAB(10);"A"; TAB(20);"B"; TAB(30);"C"
```

works on the Apple IIe and ImageWriter II, provided that you precede it with a Tab Enable statement. For example

```
PRINT CHR$(9);"T E"
```

However, the PRINT TAB statement (shown above) on an Apple IIGS and an ImageWriter II results in spacing 10 or 20 spaces rather than tabbing to those columns. When using PRINT TAB for screen formatting, there is no such problem.

The reason for this is that, when printing hardcopy, PRINT TAB appears to be tabbing the specified spaces from last character. For example:

```
50 PRINT TAB (20);"Column 20";TAB (40);"Column 40"
```

causes the first tab to be placed at column 20, but the second tab is placed at column 68. Here's why. The first tab statement puts the cursor at column 20. Because the Tab Enable statement defines each tab as 9-characters wide, the tab extends from column 20 to column 28 (one character at column 20 with the remaining 8 characters pushing the last character out to column 28). When the TAB 40 statement executes, 40 spaces are added to the last cursor location (column 28), placing the cursor at column 68.

There are two ways to handle this problem on the Apple IIGS. The first way is use the HTAB statement to format columns correctly:

```
40 HTAB 40:PRINT "Column 40":HTAB 60: PRINT "Column 60"
```

Old Apple II manuals state that this is not possible, but HTAB works correctly on the Apple IIGS, both on the screen and on the printer.

Overall, TAB and HTAB work as expected on the screen. When TAB and HTAB are used for printing, three factors must be considered:

- The type of Apple II.
- The interface card through which printing takes place.
- The active printer.

Each of these variables affect the TAB and HTAB commands when used in printing.

The second way to handle this is with the "A" command. Page 92 of the "Apple IIGS Firmware Reference Manual" states that the "A" command ('A'pplesoft Tabbing) duplicates the function of the "T" command of the Super Serial Card. Issuing this command makes the TAB command work as you would expect when using a printer.

Note: The command name ("A") was changed to avoid a conflict between "T"erminal mode and "T"abbing.

GS/OS Disk Drive Anomaly

Revised: 5/25/89
Security: Everyone

GS/OS Disk Drive Anomaly

=====

This article last reviewed: 13 April 1989

This article describes a configuration in which GS/OS thinks disks are locked when they aren't or unlocked when they aren't. To see the problem "live", try the following on an Apple IIGS with one or two 3.5-inch disk drives and one 5.25-inch disk drive all daisy-chained from the SmartPort.

- 1) Start GS/OS on the 3.5-inch drives.
- 2) Insert a locked 5.25-inch disk into its drive and put it on the desktop.
- 3) Remove the 5.25-inch disk.
- 4) Insert a write-enabled, 5.25-inch disk and mount it on the desktop.
- 5) Copy the locked 5.25-inch disk onto the unlocked 5.25-inch disk. When the copy process ends, try to rename the unlocked 5.25-inch disk.

The Finder thinks the disk is locked. The problem appears to be with the driver for the 5.25-inch drives and seems to be related to how GS/OS sees 3.5-inch disks. If a 3.5-inch disk is unlocked, then the "Get Info" for all 5.25-inch disks displays "Unlocked", whether the 5.25-inch disk is physically locked or unlocked. Conversely, the same is true for a locked 3.5-inch disk. If a 3.5-inch disk is locked, then the "Get Info" for all 5.25-inch disks displays "Locked". Again, it does not matter if the 5.25-inch disk is physically locked or unlocked.

The workaround for this problem is to make sure that your 3.5-inch disks are not write-protected. This lets the user make copies and rename new 5.25-inch disks without having to restart the system.

LaserWriter IINT: MS-DOS PC Printing Problem

Revised: 3/4/90
Security: Everyone

LaserWriter IINT: MS-DOS PC Printing Problem

=====

This article last reviewed: 13 April 1989

Some people have had problems printing to a LaserWriter IINT from an MS-DOS PC using Apple's LocalTalk PC card, along with the printing software included with AppleShare PC. A typical configuration includes Microsoft Word (PC) 4.0, under DOS 3.1. Printing originates at the PC and is sent to a LaserShare print server, which, in turn, prints to the LaserWriter. All connections are standard PhoneNET.

About six out of 10 print jobs from Microsoft Word fail and are flushed by the LaserShare during despooling due to an "unknown error". Note: Microsoft Technical Support (on the PC side) says that AppleTalk printing is "an unsupported network".

Interestingly enough, users don't have printing problems with other MS-DOS applications, printing directories, and so on or from any Macintoshes on the network.

This causes the suspicion that the PostScript driver in Microsoft Word may have problems with some of its commands. A number of drivers send their own libraries and even reconfigure the persistent parameters in a LaserWriter. Assuming the LocalTalk cabling and node have been tested along with the LocalTalk PC card for any problems, the source of the problem is the PostScript driver from Microsoft Word.

If you study some of the driver output from various PC packages, you will find that they define huge libraries of commands and even change the parameter-RAM settings. Part of the problem is that the PC software drivers expect to have the LaserWriter connected serially and set the LaserWriter or expect the LaserWriter in a configuration all to themselves. This means that the memory taken up by Macintosh Prep libraries may not let all of the libraries of PostScript code from the PC driver load. This may be what is happening here. To beat the problem, try the following:

- 1) Try a LaserWriter IINTX with memory expanded to at least 4MB.

- 2) Try printing to the LaserWriter just after a powerup and when no other Macintoshes or PCs are printing. This should show if the problem is with the different drivers from the PCs and Macintoshes.
- 3) Print the documents to an Epson printer from the application and configure the AppleShare PC printer connection for Epson emulation. This produce PostScript code from the AppleShare PC drivers. These are known to be compatible with Apple's Macintosh drivers.

LaserWriter: Problem Printing from WordPerfect (PC) Over TOPS

Revised: 3/4/90
Security: Everyone

LaserWriter: Problem Printing from WordPerfect (PC) Over TOPS

=====

This article last reviewed: 13 April 1989

Some users have had a problem using WordPerfect on a TOPS network. When they try to print from WordPerfect to a LaserWriter from an IBM PC, the LaserWriter prints a bitmap, instead of PostScript.

The problem is not with TOPS, LocalTalk, or the printer. Rather, this situation calls for a software reconfiguration. Here's why:

- 1) The printer is printing the document.
- 2) The TOPS card is making the connection.
- 3) The LaserWriter in PostScript mode only prints PostScript commands.
- 4) Because the document is printing, the PostScript driver from WordPerfect is working.
- 5) Because the printer is printing, the TOPS card is connecting to the network.
- 6) What does "bitmap" mean? A PostScript printer only prints the PostScript commands sent to the printer. If a bit-mapped image is sent using PostScript commands, then this is due to the PostScript driver. It may be that the customer's document is using a font that is not available or is creating a new font for itself that is a bit-mapped font.

The Macintosh prints correctly when printing to the LaserWriter because of our font support, both in the driver and the LaserWriter. A different set of fonts is usually used in the PC world. Another possibility is that the LaserWriter prints a bitmap of graphics when set in the Hewlett-Packard LaserJet Plus mode. To print, a Hewlett-Packard driver must be selected from the application.

As you can see, the problem is more than likely a configuration of the application and, possibly, the WordPerfect driver itself. Connect to the LaserWriter with a serial connection, and see if the problem remains. If it does, contact WordPerfect's technical support.

Apple IIe: Two Ways to Make it into AppleTalk Workstations

Revised: 5/25/89
Security: Everyone

Apple IIe: Two Ways to Make it into AppleTalk Workstations

=====

This article last reviewed: 13 April 1989

There are two ways to make an Apple IIe with a 5.25-inch drive into an AppleTalk workstation. The first is to start the Apple IIe systems over the network. The second method is to use a 3.5-inch disk drive temporarily to build a startup disk. (Workstation Card software is shipped only on a 3.5-inch disk.)

Option 1: Startup Across the Network

With this option, there is no need for the 5.25-inch drives or the Workstation software. Just prepare the AppleShare file server for use with Apple II computers. With that done, users with Apple IIe/Workstation Card systems need only power on with no disks in the drives. The computers start across the network. Having the 5.25-inch drives lets users copy files to their own disks to take home.

Option 2: Building a Local Startup Disk

This second option uses the 5.25-inch drive for local starting. The Workstation Card software ships on a 3.5-inch disk, because of software space requirements. However, you can build a workable 5.25-inch disk. This requires use of a 3.5-inch drive while building the 5.25-inch disk. Once the 5.25-inch disk is built, the 3.5-inch drive is not necessary for running the labs. The following files are the absolute minimum for a network start-up disk:

- PRODOS
- ATINIT
- SELECTOR.SYSTEM
- System.APPS
 - LOGOFF
 - LOGON
- BASIC

In this configuration, SELECTOR.SYSTEM displays several applications from which to choose. However, only the "File Server Log On", "File Server Log Off", and "ProDOS BASIC" items actually run programs. All other choices display an error message. When acknowledged, the error message returns to the SELECTOR. Unfortunately, the applications list in the SELECTOR window cannot be changed.

With the above files on the 5.25-inch disk, the student may log on, log off, and enter Applesoft BASIC. If leaving the student in BASIC is satisfactory, this is all that is needed.

If Aristotle is used for a menu system, you will need a 3.5-inch drive to transfer the Aristotle programs to the server. Once the Aristotle programs have been moved to the server, saving a one-line Applesoft BASIC program to the 5.25-inch will let the student access the Aristotle program. The program should look something like:

```
10 PRINT CHR$(4);"-/PRODOS.SERVER/ARISTOTLE/MENU.D/DISPLAY"
```

Save this one-line program as "MENU". To use it, select "ProDOS BASIC" in the SELECTOR window, and the Applesoft prompt appears. Then type "-MENU" to get the Aristotle menu. Here is the structure of the Applesoft program:

```
PRINT CHR$(4);      -- to let an immediate command be executed
"-                  -- run the program at the end of this pathname
/PRODOS.SERVER      -- name of the AppleShare file server volume
/ARISTOLE           -- name of the subdirectory containing Aristotle programs
/MENU.D             -- name of the subdirectory containing Display
/DISPLAY"           -- name of the Aristotle menu program to run
```

Apple II Workstation Card: Workstations and Zones (2/97)

Revised: 2/12/97
Security: Everyone

Apple II Workstation Card: Workstations and Zones (2/97)

=====

Apple II Workstation Card: Workstations and Zones (2/97)

Article Created: 25 May 1989
Article Reviewed/Updated: 12 February 1997

TOPIC -----

This article discusses the ways in which the Apple II Workstation Card understands zones and network IDs. Some of the discussion refers to the following setup diagram:

DISCUSSION -----

Setup:

The only zone-related limitation concerns starting an Apple II diskless workstation. The ProDOS-prepared AppleShare server must be within the same zone as the diskless workstation. Once the Apple II has started over the network, the Workstation Card and the Apple IIGS are fully aware of zones and network IDs. This means that, once started, the Apple II can log on any ProDOS-prepared, AppleShare file server in any zone available on the Internet. The number of bridges or zones does not affect the access to another server.

When the Apple II broadcasts an AppleTalk Transaction Protocol (ATP) request,

this ATP request is sent across the entire zone in search of a file server with boot blocks. In the given example, both 'net#1' and 'net#2' are in the same zone, "zone1". The FastPath passes zone broadcasts from either "net#1" or "net#2" to the other.

Once startup is completed, the AppleShare II Workstation software is executed. From this application, the user can choose the appropriate zone and log on to the desired ProDOS-prepared server. At this time, Name Binding Protocol (NBP) translates the names into the associated Internet socket addresses of the corresponding network entities. In this case, the Apple II workstation name is translated to an address, and the server name is translated to an address. These addresses notate network IDs, zone IDs, bridge IDs, and network entity IDs.

When a workstation is instructed to print, it looks for the chosen printer with the address provided by NBP. The address specifies the location of the printer. Because the printer is on "net#2" (the same network as the Macintosh SE), the FastPath determines that the address belongs on "net#2". The FastPath does not accept the traffic, because the address is local to "net#2". However, when the Apple II requests service from the server, the FastPath recognizes the address as one that belongs to "net#1". In this condition, the FastPath lets the request travel over the bridge to the server.

Typically, routing is handled at the fourth OSI layer, the transport layer of AppleTalk. Manufacturers working with AppleTalk use the transport layer to handle routing. Manufacturers working with other protocols may handle routing at a higher layer in the OSI model.

HyperCard: Problems Sending Sounds On AppleTalk

Revised: 5/25/89
Security: Everyone

HyperCard: Problems Sending Sounds On AppleTalk

=====

This article last reviewed: 14 April 1989

Reports have appeared of problems with HyperCard sending sounds over a network. The sounds break up badly when they arrive at a workstation. This includes sounds accessed from CD-ROM. Also, network performance slows noticeably when sounds are being transmitted.

Some people have guessed that the breakup of the sound is due to clipping of packets, but this is not the case. If packets were being clipped, there would be no sound played at all. When AppleTalk receives an incomplete packet, it throws the packet away and requests a retry. If the packet is thrown away, HyperCard would never know the packet had been sent.

The breakup is due to the sounds being shipped in packets. In tests, the sound starting and stopping correlates to the beginning and the ending of packets. This is especially true with longer sounds, such as musical passages.

Applications used across the network need to take into account the limits of the network. Other performance difficulties have appeared in other applications not designed for network access. Ethernet speed may solve this particular issue. However, to achieve the best performance, an application needs to be designed for the network environment. Long, digitized sounds being transmitted over the network are less than ideal for network-application design.

One approach to using long music passages in HyperCard is to keep the music passages on local storage. HyperCard looks first for the requested resource in the stack, next it looks in the Home card, then in HyperCard itself, and finally in the system. If the required sounds are installed in a local Home stack, the breaking up of the sound does not happen. If these sounds are stored locally, you must remove them from the stack residing on the server. Because HyperCard looks at the current stack first, the sounds in the server stack are used, unless removed.

If the applications have not been optimized for multiuser network access, a drop in network performance would not be unusual. Additionally, the AppleCD SC has a slower access time than the typical hard drive that is used as an AppleShare server.

HD80 SC: Format With Either A/UX or Macintosh OS

Revised: 9/29/90
Security: Everyone

HD80 SC: Format With Either A/UX or Macintosh OS

=====

This article last reviewed: 14 April 1989

All the HD80 SCs used by Apple have the same level of firmware (Quantum ROM rev. B). The quantity of bad blocks may vary from one disk to another, but this is transparent to the user.

More specifically, any Apple HD80 SC can be formatted for use with either A/UX or the Macintosh OS. It is possible that drives displaying larger numbers of bad blocks are older drives and, therefore, have more bad blocks due to time. However, all of the drives should format to the same volume size under either operating system.

Editing troff Files In the Macintosh OS

Revised: 9/24/92
Security: Everyone

Editing "troff" Files In the Macintosh OS

=====

Article Created: 18 April 1989

Article Change History

08/31/92 - REVIEWED
 o For technical accuracy.

08/31/92 - UPDATED
 o To include A/UX 3.0 Information.

TOPIC -----

Currently, you cannot do the following process:

- 1) Use "troff" on a UNIX 4.3 system to generate "troff" files.
- 2) Transfer these files to a Macintosh for editing with MacWrite or similar application under the Macintosh OS (on a non-A/UX system).
- 3) Ship these files, once edited and modified, back to the UNIX system as "troff" files.

DISCUSSION -----

The problem is in the way that "troff" and Macintosh word-processing applications specify document format within a file. They are quite different and not understood by one another.

Although transferring a "troff" file, which has been converted to PostScript, is possible, once the document is opened by a Macintosh application that understands PostScript, its format cannot be changed.

If know of a way to do this, please forward the information to TECH.COMM for evaluation and review.

..TIL03838-Editing_troff_Files_In_the_Macintosh_OS_(TA39929).pdf

In A/UX 3.0, you may now print postscript files from the Macintosh to a postscript printer using the lasarwriter font utility.

MousePaint On 3.5-Inch Disk: Must Be Named /MOUSEPAINT

Revised: 5/25/89
Security: Everyone

MousePaint On 3.5-Inch Disk: Must Be Named /MOUSEPAINT

=====

This article last reviewed: 18 April 1989

When copying the MousePaint program onto a 3.5-inch disk, for use with the Apple IIc Plus for example, be sure the new disk is named /MOUSEPAINT.

If the disk has any other name, it will not start up: the program gets to the "Welcome to MousePaint" screen and then scans down to the Disk IIs that are connected. When it comes back to the 3.5-inch drive, it gives an error message "Path Not Found". The next line says "Break in 10" and displays the bracket prompt.

Another solution is to set the pathname in the startup program MP.START on the MousePaint disk. Either of these solutions works; the first is easier.

LaserWriter Landscape through AUTOEXEC.BAT

Revised: 12/6/89
Security: Everyone

LaserWriter Landscape through AUTOEXEC.BAT

=====

This article last reviewed: 18 April 1989

This article describes how to use the AUTOEXEC.BAT file make it possible for you to choose whether to print landscape or portrait. It assumes you are using a LocalTalk PC card, LaserWriter software, and AppleShare PC (1.1) print drivers, so you can access the printer directly from Lotus 123 and Microsoft Word.

Here is a typical AUTOEXEC.BAT prepared for use with AppleShare:

```
atalk /mem=7K
\ashare
\aprint
\minses
\redir
\anet auto
\MOUSE1\mouse
\MOUSE\cpanel
@echo off
path=c:\;c:\dos;c:\lwdir;c:\ashare;c:\3270
prompt $P$G
lwprint -a postscrp.ini
PATH C:\WINDOWS;c:\;c:\dos;c:\lwdir;c:\ashare;c:\3270
```

The confusing part about printing Landscape is that it is not a mode. Drivers take the information going to the LaserWriter and massage everything necessary to rotate it on the printed page. The printer never gets set to a Landscape "mode".

To be able to flip between Portrait and Landscape, remove the line that begins with "lwprint" from the .BAT file. Then, use the DA pop-up application that is provided with AppleShare PC to set up the printer.

Using this method, you must print the desired file to a text file. At this point, you have two choices:

- If you choose to print to the LaserWriter through the Epson emulator (in the DA application), you need Sideways or an equivalent program to rotate the output.
- If you have chosen not to use the emulator, you must use the LWASC-R <filename> command in a batch file. This command is described on page 102 of the "AppleTalk PC Card Manual".

LaserWriter IINTX: Compatible SCSI Drives

=====

This article last reviewed: 18 April 1989

Adobe submitted the following list of drives tested by them and known to work with the LaserWriter IINTX:

Seagate ST225N
Rodime 650 series (R0651, R0652, R0751, R0752)
Quantum Q200 series (Q250, Q280)
MiniScribe 8425-SCSI
MiniScribe 80515

Other drives using embedded SCSI controllers have been reported compatible but have not been tested by Adobe. For more information on this topic, see the November 15, 1988 issue of "MacWeek".

Parallel Printer On AppleTalk

Revised: 7/23/92
Security: Everyone

Parallel Printer On AppleTalk

=====

Article Created: 31 May 1989
Article Last Reviewed: 18 April 1989
Article Last Updated: 22 June 1992

If you need Centronics parallel-compatibility on a network, consider products offered by Solana Electronics. Solana Electronics markets devices that are designed to connect, for example, a Printronix printer (with a Centronics interface) to an AppleTalk network.

However, purchasing an R-Server to connect a relatively inexpensive dot-matrix printer to the network costs more than replacing that printer outright with a new ImageWriter. Furthermore, after connecting an Epson to the network via an R-Server, you have no "network" driver support providing even minimal graphic support. All you have are the printer's built-in fonts with minimal or no formatting of text.

Solana has several options. If the printers are serial, consider the Solana R-Server X810.1 or X810.2. If the printer is parallel, use the X810.2. The X8120 devices can be set up with up to 2MB of memory for use as a data buffer to store and forward messages and so on.

Editor's Note 22 June 1992: Solana has discontinued business to our knowledge, so we are unable to refer you to them directly for further information.

System 6.0.2: Microsoft InterMail Incompatibility

=====

This article last reviewed: 18 April 1989

There is an incompatibility between Microsoft InterMail and System Software 6.0.2 or later. Version 1.36 of InterMail gives unpredictable performance with System software 6.0 or 6.0.2. Symptoms include unexpected and unpredictable lockups and/or system bombs (including those that happen while saving).

Microsoft has released a patch to fix InterMail versions 1.35 and 1.36, so they would work with System 6.0 and System 6.0.2. Reports from the field indicate the patch works correctly.

Here is a description of this problem:

After upgrading to System 6.0.2, intermittent problems occur as system bombs (mostly ID=03 and a few ID=02) when using Microsoft Word or Microsoft Excel and executing a "Save" or "Save As" menu option (75% of reports). Occasionally, a Print command (25% of reports) also causes a system error.

This is occurring on about seven to 10 machines that use Microsoft Word or Excel very heavily. All users are using Microsoft Word 3.01, Microsoft Word 3.02, or Excel 1.5 and operating under Finder, rather than MultiFinder. The errors occur uniformly across the population and are not isolated to one vendor's hard drive.

Videodisc Driver Information

=====

This article last reviewed: 18 April 1989

Whitney Systems has a Macintosh HyperCard Videodisc driver package called Videodisc Writer. It is an easy way for customers to incorporate videodiscs into their HyperCard stacks without having to learn HyperTalk or how to write XCMDs or XFCNs. It presently supports the Pioneer 4200, 6000, and 6010 Videodisc players. Whitney Systems is willing to write an interface for other players, too, should there be sufficient demand.

For more details, search the Tech Info Library under "Whitney Systems".

Note: "Videodisc" is spelled with a "c" at the end and is all one word. This was established with the original Phillips/Sony patent on Videodisc and Compact Disc. If you are referring to magnetic media, then spell "disk" with a "k", as in "floppy disk". If you are referring to read-only media, spell "disc" with a "c", as in "compact disc".

Macintosh: Tandy 100 and 102 Connectivity

Revised: 6/17/92
Security: Everyone

Macintosh: Tandy 100 and 102 Connectivity

Article Created: 18 April 1989
Article Last Reviewed: 9 June 1992
Article Last Updated: 9 June 1992

TOPIC -----

I need to connect a Macintosh to a Tandy Model 100 and to a Tandy Model 102 portable computer for our work group.

DISCUSSION -----

Connecting a Macintosh computer to a Tandy Model 100 or Tandy Model 102 portable computer requires a cable and communications software. Here are the pinouts for the cable:

- Macintosh 128K, Macintosh 512K, and Macintosh 512Ke to Tandy Model 100 and Tandy Model 102 cable:

Macintosh (DB-9 male)	Tandy (DB-25 male)
-----	-----
3	7
5	3
7	6, 8, and 20 (tied together)
9	2
	4, 5 (tied together)

- All other Macintosh models (from Macintosh Plus onward) to Tandy Model 100 and Tandy Model 102 cable:

Macintosh (Mini-Circular 8 male)	Tandy (DB-25 male)
-----	-----
2	6, 8, and 20 (tied together)
3	3
4	7
5	2

4, 5 (tied together)

Note: A Macintosh (DB-9)-to-ImageWriter I cable (Service Part #590-0169) properly connects a Macintosh 128K, Macintosh 512K, and Macintosh 512Ke to the Tandy Model 100 and Tandy Model 102 computers. The same cable connects the Macintosh Plus, Macintosh SE, and Macintosh II to the Tandy Model 100 and Tandy Model 102 computers, if used in conjunction with the Macintosh Plus Peripheral Adapter Cable (Service Part #590-0341 or #590-0553).

Using this custom cable and a terminal program for the Macintosh, you should be able to transfer files between the Tandy computers and the Macintosh with no difficulty. The Macintosh will think it's talking to an external modem; the terminal program will let you "talk" to the Tandy computers, or upload or download from the Tandy computer as if it were a mainframe. The Tandy, of course, uses its built-in TELCOM program in the TERM mode and can upload and download files, as if it were talking to a mainframe.

The communication parameters must be the same at each end: baud rate, stop bits, XON/XOFF, and so on. A commonly used parameter for the Model 100 is 7711E for 4800 baud, 7-bit, Ignore parity, 1 stop bit, and XON/XOFF enabled (although you could choose other baud rates or other parameters).

LaserWriter: How To Use Preprinted Letterhead

Revised: 12/6/89
Security: Everyone

LaserWriter: How To Use Preprinted Letterhead

=====

This article last reviewed: 18 April 1989

Apple has no documented specifications for paper or ink requirements when working with preprinted letterhead and logos, beyond the information in the "LaserWriter II Owner's Guide". Below is a copy of this specification.

"16-lb. to 20-lb. photocopy or typewriter bond (60 to 80 g/m2) in normal mode; up to 36-lb. (135 g/m2) stock in manual mode with face-up tray open. Accepts most letterhead and colored stock. Accepts medium-weight photocopy transparencies. Envelopes can be printed with manual feed or from the envelope cassette. Labels can be printed using manual feed."

However, any paper or ink used with the LaserWriter must be able to withstand the temperature of the fuser roller. This temperature varies between 165 and 180 degrees centigrade. It takes an 8.5-inch by 11-inch piece of paper approximately 5.8 seconds to travel over the fuser roller or approximately 1.5 inches per second.

Aristotle: Improper Updating Of User List

=====

This article last reviewed: 18 April 1989

This article discusses why Aristotle users continue to appear in Menu Management and how to fix this problem. They are present, because the Access Privileges are not set properly on the Any User folder that is in the Users folder.

Within the Users folder is a folder called Any User. Within the Any User folder is a folder called ESP. Within that folder is a file called "userlist". "userlist" contains the current Aristotle Menu Management user list. If the privileges are set improperly on the Any User folder and the enclosed ESP folder, the "userlist" file cannot get updated. The userlist in ESP gets updated from the "userlist" in the server folder. AppleShare checks the dates of the two files and updates whichever file has the older date. If the userlist is not updated, the old users remain, and the new users don't show up.

To clear up this problem, change the Any User Access Privileges to See Folders, See Files, and Make Changes to everyone. Then change the ESP Access Privileges to See Folders, See Files to everyone. Make sure that the Teacher owns the Any User and the enclosed ESP folder. Then launch Aristotle Menu Management.

For more details, this entire case is documented in the "Aristotle Administrator's Guide", starting on page 66.

Macintosh: Wang VS Connectivity Issues

Revised: 5/31/89
Security: Everyone

Macintosh: Wang VS Connectivity Issues

=====

This article last reviewed: 23 April 1989

This article discusses problems with connecting Macintoshes to Wang VS processors. The client is currently doing terminal emulation and file transfer on local and remote Wang VS processors. After some experimentation, they have attached a NetSerial modem to their AppleTalk network (using LocalTalk) with a customized version of VS Term. They are connected to the Wang VS through a WACS controller and use the RS-232 cable (19.2 bps) to attach to the NetSerial.

This solution is too slow for them, particularly when doing file transfers. The slowness in the network is due not to LocalTalk (LocalTalk transmissions are 230.4K bits-per-second), but to the RS-232 connection running at 19.2K bits-per-second. This means the RS-232 segment of your connection to the Wang is running 12 times slower than the LocalTalk.

There might be a way to connect Macintoshes to the Wang via Ethernet, but there are some prerequisites. NCSA Telnet from the University of Illinois' National Center for Supercomputer Applications, or NetOne from Ungermann-Bass, must be used on the Macintosh to make a VT100-emulation connection through TCP/IP and FTP communications. These packages are compatible with LocalTalk or EtherTalk for the Macintosh.

Connecting the Macintoshes to the Wang Ethernet is fairly straightforward using Kinetics FastPaths, Cayman GatorBoxes, Apple EtherTalk cards, or any of the various Macintosh Ethernet connectivity units from Kinetics.

The difficulties are with the Wang system, itself. The following questions must be resolved before the above solution can be implemented:

- 1) Does the Wang VS system use TCP/IP and FTP? If it uses WangNet, then these communication protocols will not work.
- 2) Can terminals be connected through the Ethernet? Some office systems may implement Ethernet for file transfers only and have no facilities

for handling remote terminal connections across the Ethernet.

Security: Everyone

HyperCard: Freeing Up Memory

=====

Article Created: 23 April 1989
Article Last Reviewed: 4 June 1992
Article Last Updated: 4 June 1992

TOPIC -----

I find myself frequently running low on memory when in HyperCard. Sometimes it won't launch all.

DISCUSSION -----

There are various things you can do to free up memory for HyperCard. When running under System 6, consider running HyperCard without MultiFinder turned on. In System 7 turning off MultiFinder is not an option; for this case, consider purchasing more RAM for your Macintosh, especially if you currently have only 2 MB. Also, adjust the current memory setting for HyperCard to at least 1000K, depending on the size and complexity of the stacks you will be using. Some other suggestions for freeing up memory are given below.

- Minimize use of INITs, extensions, and control panels, moving them out of the System Folder if necessary. Specifically, watch for memory-hungry items such as macro programs (QuicKeys, MacroMaker, and so on), and those that create a desktop picture (like ColorDesk).
- Don't run HyperCard simultaneously with AppleShare, InBox, or other memory-intensive applications.
- Turn the RAM cache as low as possible - in System 6, you can even turn it off.
- Run in two-color mode.
- Don't use huge beep sounds.

..TIL03857-HyperCard-Freeing_Up_Memory_(TA39945).pdf

- Don't call lots of XFCNs/XCMDs within HyperCard.
- Empty global variables when no longer needed.

Macintosh: HP150 Connectivity

Revised: 5/31/89
Security: Everyone

Macintosh: HP150 Connectivity

=====

This article last reviewed: 23 April 1989

You can pass ASCII files between a Macintosh computer and a Hewlett-Packard HP150. To do this, you need a software package named "Reflection" from Walker, Richer, and Quinn, Inc. Although Reflection can do binary file transfer, the HP150 binary files are not usable on the Macintosh without a translator.

There are two physical methods for connecting Macintosh and HP150. First, a null modem cable can be used for a direct connect between the two computers. Reflection supports both Kermit and Xmodem. Reflection, running on both the Macintosh and the HP150, can transfer files in either direction.

The second method requires an Hewlett-Packard minicomputer, like an HP3000. Both Macintosh and HP150 then connect through Reflection to the HP minicomputer. The Macintosh and HP150 use the HP minicomputer as a central location for holding the files being transferred.

Note: The HP150 is not quite an MS-DOS machine. The operating system is a Hewlett-Packard design. The 3.5-inch disk drive is not formatted like MS-DOS, OS/2, or Macintosh.

For more details, search the Tech Info Library under "Walker, Richer, and Quinn, Inc."

AppleCD SC: Audio Questions (3/95)

=====
Article Created: 23 April 1989
Article Reviewed/Updated: 2 March 1995

TOPIC -----

This article provides questions and answers about AppleCD SC audio.

DISCUSSION -----

Question: Is the player oversampling; if so, what is the rate?

Answer: The AppleCD SC samples at the normal 44.1 KHz rate.

Question: Does it have an analog, digital, or combination output filter?

Answer: The AppleCD SC does have digital and analog filters; the analog filter is a "Brickwall" or steep analog filter.

Question: What is the output of the CD player in volts?

Answer: The mini-stereo jack outputs 0.6 +/- 0.1 volts RMS, at 32 ohms. The RCA plugs in the back output 0.5 +/- 0.1 volts RMS, at 47K ohms.

Question: Are the audio output sections of the player discrete?

Answer: The audio sections of the AppleCD SC are not discrete.

AppleShare: Responding to System Crashes and ID=29

=====

This article last reviewed: 23 April 1989

This article describes what to do about AppleShare system crashes that give an error ID=29 and restart as the only option.

When an error occurs on the file server, AppleShare tries to react to the error. If successful, it does some general housecleaning before reporting the error to the user as error 29. This housecleaning includes writing buffers to disk and closing open files, like the PDS file.

Because the server is reporting errors, use the AppleShare Admin program to verify the volumes for consistency. It is also possible that there is a problem with the file server hardware. It may be prudent to verify the integrity of the hardware. If the errors continue, it may be necessary to rebuild the server from scratch.

Macintosh: Proper Way to Shutdown and Restart

=====

Article Created: 23 April 1989

Article Change History

09/28/92 - REVIEWED
• For technical accuracy.

TOPIC -----

Is it okay to shut down my Macintosh by turning off the power?

DISCUSSION -----

The only correct way to restart or shut down a Macintosh system is to use the "Restart" or "Shut Down" commands from the "Special" menu in the Finder. On startup, when a volume is mounted successfully, a flag is set on that volume telling the system that the volume was mounted properly.

When the volume is unmounted properly by using the "Restart" or "Shut Down" commands in the Finder, this flag is cleared. If the computer is turned off by the power switch or reset using the reset button, the volume has been unmounted improperly, and this flag is not cleared.

During startup, this flag is tested. If the flag is clear, the volume was unmounted properly, and the system starts up as normal. If the flag is set, the system knows that the volume was unmounted incorrectly. The system then proceeds to rebuild the volume bitmap. On a large volume with many files, this operation may take several minutes.

A/UX 1.0 and 1.1: f77 Compiler Problem (8/94)

Revised: 8/23/94
Security: Everyone

A/UX 1.0 and 1.1: f77 Compiler Problem (8/94)

=====

Article Created: 24 April 1989
Article Reviewed/Updated: 19 August 1994

TOPIC -----

This article describes a major problem in the A/UX f77 compiler as it exists in A/UX 1.0 through A/UX 1.1 (including A/UX1.1Beta1). NOTE: This problem is fixed in A/UX 2.0 and 3.0.

DISCUSSION -----

The compiler incorrectly allocates common on the stack when it should allocate it in the data segment. You can force it to allocate the common block in the data segment by using a data statement, but this also causes problems.

As an example, try this program, first as a single file and then split into two files.

```
program test1
common /fred/ array
integer array(2)
save
array(1)=55
array(2)=66
print *, 'Array in main is ', array
call sub1
print *, 'Array after call to sub1 is ', array
stop
end
*
subroutine sub1
common /fred/ array
integer array(2)
save
print *, 'Array in sub1 is ', array
return
```

end

The problem keeps S from running under A/UX. Here are tests with A/UX 1.0.1 and A/UX 1.1Beta1:

A/UX 1.0.1

a) Source in same file (f77 foo.f):

Array in main is 55 66
Array in sub1 is 55 66
Array after call to sub1 is 55 66

b) Source in two files (f77 foo.f bar.f):

Array in main is 55 66
Array in sub1 is 55 66
Array after call to sub1 is 55 66

A/UX1.1Beta1

a) Source in same file (f77 foo.f):

Array in main is 55 66
Array in sub1 is 55 66
Array after call to sub1 is 55 66

b) Source in two files (f77 foo.f bar.f):

Array in main is 55 66
Array in sub1 is 0 0
~~~~~  
Array after call to sub1 is 55 66

TOPIC -----

A user has found (using very sophisticated photometric devices) that when he generates a monochrome palette from a color palette, some of the tones are identical. This article discusses this phenomenon.

DISCUSSION -----

In regard to using the color palette, the Palette Manager does not place new colors into the display device's color look-up table (CLUT). It maps the requested colors in a palette to available colors within the current color table. The correct method for using specific color values is to use the Color Manager calls to create and load a programmed color table.

There are some other points that must taken into account after setting your colors with the Color Manager.

- It is possible to produce grays by setting the monitor to monochrome output and not setting grays, as the user in question probably does. When selecting monochrome from the monitor's Control Panel CDEV, luminance mapping of the colors in the color table is done to calculate and replace the RGB values for a monochrome pixel. The luminance mapping follows this equation:

$$\text{Luminance} = .3 * \text{red} + .59 * \text{green} + .11 * \text{blue}$$

The resulting value is placed into the display device's table for R, G, and B. The values are altered according to the above equation. This needs to be taken into account if the monochrome option is chosen for the Apple High-Resolution Color Monitor.

- If you place your own RGB "gray" values into a color table, you must also take into account gamma correction. Gamma correction is done by the display device's driver to correct the disproportionate light output of the CRT phosphors by comparison with the proportional input voltages of the video signal. To set a linear relationship between colors and output, the values set for the Macintosh II Video Card are changed to new values, which then produce the corrected color output on the monitor. Test equipment detects a gamma-filtered set of values from the monitor.

The gamma correction is automatically handled for all values written to the device's color table. This is based on an empirically-derived gamma look-up table. If the selected values fall within the same look-up table reference, they can be mapped to the same gamma value. This would explain why some values are the same. The gamma table ID is located in the SCRN resource of the System file for the Macintosh II Video Card. A new GAMA Resource table can be defined and installed in the System file for use by the Macintosh II Video Card. To use the new gamma table, the GAMA resource ID must be changed in the SCRN resource to that of the new table.

The safest values for any testing will probably be a linear table that does no gamma correction. A quick and easy way to do this is to pass -1 to the SetGamma Control parameter block as the new table address. This causes a linear table to be used, guaranteeing that all of the possible gray levels of the card are available. At that point, the actual color output on the monitor depends on the phosphors themselves, which have a variance from monitor to monitor of +/- .02 for the red and green phosphors and +/- .015 for the blue. The CIE coordinates of the phosphors are:

Red: x=.625 y=.34 Green: x=.28 y=.595 Blue: x=.155 y=.070

To properly set the gamma table, see the information below about how the driver uses this table. You should also investigate how to control device drivers. This is described in "Inside Macintosh Volume II." Another source of information is the "Designing Cards and Drivers Manual for the Macintosh."

#### Gamma Information

-----  
In the current implementation of the video drivers, gamma correction is applied to requested, absolute colors, immediately before they are set in the color look-up table by the SetEntries control call. More specifically, some number of high-order bits are extracted from the red, green, and blue channels and used as an index into tables of corrected values. These values are then placed into the hardware, yielding corrected output. On the Macintosh II Video Card (the TFB card), the high eight bits of each channel are used to reference the gamma table.

There are a number of minor shortcomings in this implementation. First, there is not absolute symmetry between the SetEntries control call, which sets the CLUT, and the GetEntries status call, which reads the CLUT hardware, because the gamma correction took place as part of the SetEntries call. Also, the uncorrected values are generally unrecoverable (although a copy of the absolute colors are always available in the

GDevice structure).

Finally, it is most desirable to extract more bits as an index to the gamma table than the number of bits of color information that will be set in the CLUT. This way, you avoid a loss of color resolution after correction. For example, the TFB card has an eight-bit-per-channel CLUT, but only uses the most-significant eight bits of the (16-bit) channel information for gamma lookup. At lower intensities, the gamma correction increases the distance between adjacent values. As a result, on the TFB card, some dynamic range is lost at lower intensities. This could be corrected by extracting nine or ten bits of channel information rather than eight and using a larger, gamma-correction table, but this option was declined to reduce gamma table size.

#### The GammaTbl Data Structure

-----  
The structure itself has been a bit of a mystery, as it is not defined in either "Inside Macintosh Volume V" or the Designing Cards and Drivers Manual. This is the structure:

```
record GammaTable of
  gVersion: integer; {gtab version, currently 0}
  gType: integer; {drHwId value}
  gFormulaSize: integer; {size of formula data, below}
  gChanCnt: integer; {# of component channels}
  gDataCnt: integer; {# of values per channel}
  gDataWidth: integer; {size of data in tables}
  {gamma correction look-up tables}
  gFormulaData: array [0.. gFormulaSize] of byte;
  {data for gamma calculation formula}
  gData: array [0.. gDataCnt] of byte;
end;
```

In this structure, gVersion represents the gamma table format version, which is 0 for all current cards. The gType field holds the drHwId value for this board to identify the board that this table was measured for. Note that this means that a single gamma table can't directly be shared between two different cards, even if they both have the same CLUT response curve (which is usually linear). This lets the data in the gamma table be in an appropriate form for varying hardware (that is, a card could have four-bit/channel DACs and might prefer gamma data in the range \$0..\$F rather than \$0..\$FF).

gFormulaSize defines the number of bytes occupied by the gFormulaData field. On Apple's current video cards, gamma correction is done by modifying the values loaded into the CLUT by the SetEntries control call to approximate linear response on the display. On these systems, the gamma correction table acts as a final, look-up, data table, which translates the requested color into closest available linearized level. These gamma table values are determined empirically by measuring the output of a calibrated display.

More sophisticated systems may choose an alternative to this simple

look-up mechanism. For instance, you can calculate gamma correction factors based on a mathematical response function. By default, the TFB card uses a single correction table for all three channels. No calculations are performed on the incoming color table other than simple lookup. Cards can remember the specific monitor configuration at the beginning of the gFormulaData field, allowing it to identify and use only gamma tables developed for the currently connected monitor.

gChanCnt is the number of look-up tables in gData, below. If there is more than one channel of gamma correction data, then the R, G, and B tables follow each other, respectively, at the end of the structure.

gDataCnt is the number of discrete look-up values included in each of the channel's correction table. It is always equal to 2gDataWidth, but refers to number of bytes that this channel's data occupies.

gDataWidth describes the number of significant bits of information available in each entry in a channel's correction table. The data always appears as gDataWidth bits, right-justified in a field that is the next larger number of bytes than gDataWidth. Because it is rare to have devices with more than eight bits of CLUT resolution, virtually all devices pack their correction data into bytes.

gData is actual correction table data. If there is more than one channel's information, each table follows the next in R, G, B order. The standard tables included in Apple's driver have only one table, which is applied to all three output channels. Because Pascal cannot express variable size fields in record structures, the independent channels are not individually named.

#### "gama" Resource Format

-----  
In addition to the RAM data structure for gamma tables covered above, there is a standard resource format for gamma table resources. Like many other resource templates, the gamma structure is an image of the RAM form stored in resource format. There are no changes.

#### Using Gamma Correction

-----  
Gamma correction is always applied by the TFB video driver. At driver open time, the driver is usually initialized with a linear (noncorrecting) gamma table. When \_InitGraf is called, the "scrn" screen configuration resource is read from the System file. This resource (described in "Inside Macintosh Volume V") includes information about the size and orientation of the different monitors configured into the system, including their last video mode (pixelsize), color table, and gamma table.

If there is no "gama" resource ID specified, or the specified ID is not present, then a default gamma table, "gama" =0 is loaded from the System file and used (this is the table calculated for the TFB card). If the specified resource is found, then the appropriate resource is loaded, and a control call is issued to the driver to make this the current gamma table. Unfortunately, there is currently no tool to set the "gama" ID,

short of modifying the "scrn" resource directly.

To facilitate the use of the gamma table, there are two calls in the standard, video-driver routines that set the gamma table (control call 4, SetGamma) and retrieve the pointer to the current gamma table (status call 6 on TFB rev 2 drivers and up). These calls simply take and return a pointer to a GammaTbl structure.

HyperCard: Global Paths & Avoiding Lost Pathnames

=====

Article Created: 24 April 1989  
Article Last Reviewed: 14 July 1992  
Article Last Updated: 14 July 1992

TOPIC -----

Whenever I move various applications, stacks, and folders comprising my HyperCard projects to another hard disk, I am inundated with "Where is..." dialog boxes as my scripts try to re-find the correct paths to jump between stacks.

DISCUSSION -----

Some HyperCard developers have asked if there is any way to provide a global path command or to assign physical or logical names that initiate at startup. This becomes important when a program is moved to another machine (with different names). This kind of porting can make all the pathnames incorrect with the result, as above, that the program constantly asks for help in finding files.

Many users try to avoid this problem by beginning the path names with the actual volume name. This is not necessary.

An easier solution is to load the folders in question into the same folder that contains the HyperCard application itself, then place a colon at the beginning of the path name, like this:

:HyperCard Ideas:Idea Stacks:

The first colon in this statement tells HyperCard to look for the "HyperCard Ideas" folder within the same folder that contains HyperCard itself. HyperCard will then continue on to the "Idea Stack" folder for the chosen stack.

The problem can also be handled by getting the Long Name of the currently executing stack. This name returns the path to the stack. As long as the

other stacks or accessed files are kept in the same folder, the pathname can be manipulated to open those files. You can even place the stacks or files in subfolders, as long as the folder names are placed in the path.

An example:

Function PathWay

```
put the long name of this stack into NewName
delete char 1 to 7 of NewName
repeat
  if offset(":",NewName) is 0 then
    exit repeat
  else
    put char 1 to offset(":",NewName) of NewName after NewPath
    delete char 1 to offset(":",NewName) of NewName
  end if
end repeat
return NewPath
end PathWay
```

put PathWay () into the message

This piece of code returns the current path to the stack. By appending the name of a stack or file onto the end of the returned path, your stacks can open any stacks or files in the same folder. By placing a folder name and the name of the stack after the returned path, you can open the stacks within a subfolder.

HyperCard: Error Code 19374

=====

This article last reviewed: 24 April 1989

Error 19374 means that HyperCard was not able to dispose of all of the objects in memory. This probably means that your stack is corrupted.

To solve this problem, create a new stack and transfer all of the scripts, data, and so on from the old stack to the new stack. If the stack is large, you may want to create a script to automate this process.

## Apple Hardware: Importance of Proper Grounding (2/97)

Revised: 2/18/97  
Security: Everyone

Apple Hardware: Importance of Proper Grounding (2/97)

=====

Article Created: 1 June 1989  
Article Reviewed/Updated: 17 February 1997

TOPIC -----

This article discusses the importance of proper grounding for all Apple equipment.

DISCUSSION -----

- From the standpoint of user safety, when using the equipment, it is important to have the accessible portions of the system at a voltage potential that do not endanger the user. Without a ground, the high voltages used to drive the monitor might build up a large enough potential to cause serious shock to a user.

- When systems are not grounded, there is the possibility that a system may build up a charge, either from environmental conditions or from the voltages inside. Without a ground path for this charge to dissipate, the system could self-destruct from a serious over-voltage condition.

- If a system is not properly grounded, any peripherals connected may or may not be grounded. This could cause excessive ground currents that might cause erratic operation. Excessive ground currents could also endanger the equipment. This is the primary reason for installing Ground Fault Interruption circuits at locations where excessive ground currents would be hazardous (places like bathrooms and kitchens where water and electricity are in close proximity).

If all systems in use at any particular location are properly grounded, there is minimal possibility of user shock, system overload, and/or erratic operation. Also, many governments require certain types of equipment to be grounded for all the above reasons, although the language in those regulations is much more specific.

Macintosh: Order Of Devices Checked During Startup

=====

Article Created: 24 April 1989

### Article Change History

-----

09/28/92 - REVIEWED

- For technical accuracy.

### TOPIC -----

What is the order of devices checked by the Macintosh during startup?

### DISCUSSION -----

Here is the correct order of devices the Macintosh checks during the startup sequence:

- 1) Floppy drive 0
  - On a Macintosh II, IIX, & IIfx this is the right-side internal drive.
  - On a Macintosh SE with two floppy drives, this is the lower drive.
  - On other systems, this is the internal drive.
- 2) Floppy drive 1
  - On a Macintosh II, IIX, & IIfx this is the left-side internal drive.
  - On a Macintosh SE with two floppy drives, this is the upper drive.
  - On other systems, this is the external drive.
- 3) Floppy drive 2
  - This applies only to a Macintosh SE with a third floppy drive.
- 4) Startup device selected via the Startup Disk CDEV
  - This may include SCSI or NuBus startup devices.
- 5) SCSI devices, beginning with ID 6 and ending with ID 0.

6) NuBus startup devices.

- This applies only to a Macintosh II.

Both the "Inside Macintosh V" and the "Macintosh Family Hardware Reference" manuals state that the internal SCSI device is checked before any other SCSI device, regardless of SCSI ID. This is NOT True. Unless the internal SCSI device is selected as the startup device via the Startup Device CDEV, it has no special priority during the startup process.

## A/UX: NFS and Hard Disk Space (9/94)

Revised: 9/2/94  
Security: Everyone

A/UX: NFS and Hard Disk Space (9/94)

=====  
Article Created: 24 April 1989  
Article Reviewed/Updated: 1 September 1994

### TOPIC -----

This article describes three things you might do to free up some space on a workstation's hard disk to increase the size of the Macintosh OS partition. These include:

- 1) Changing the SWAP partition.
- 2) Moving selected files onto an NFS server.
- 3) Reclaiming disk space for the Macintosh OS, as files are transferred to the server.

### DISCUSSION -----

- 1) Under A/UX, by default, 18 MB is allocated for SWAP partition. You can change this size if you wish. Normally, if you do a large number of huge compilations or use any specific application that requires a lot of swap space to be used by the memory management, you probably need to increase the SWAP size. Typically, the swap space should be between two and three times the size of physical RAM installed in the machine.
- 2) Depending on what files you want to be shared by the users, you can move them to the NFS server. For example, you could have an NFS server contain:
  - The on-line documentation (/usr/catman).
  - The public domain software sources and binaries.
  - The common toolbox applications, such as MacWrite, MacDraw, and so on.
  - The X Window server and/or client applications.
  - The Domain Name server and/or Yellow Pages Server Database.

- 3) After you move files to the server and before you "reclaim" some space for the Macintosh OS, you need to:
  - a) Use a method like "tar" or "cpio" to back up files that will remain on that hard disk.
  - b) Use HD SC Setup software to repartition A/UX file systems. You may "customize" the entire hard disk partitions or choose the "MINIMUM A/UX" configuration option to get the minimum A/UX file system partition.
  - c) Boot A/UX from another A/UX hard disk (usually an external hard disk).
  - d) Do "mkfs" on the hard disk that was repartitioned in step b, and restore the files that were backed up in step a.
  - e) Finally, it is a good practice to do "fsck" on the newly created filesystem(s).

## DA Handler: Memory Constraints

Revised: 6/16/92  
Security: Everyone

DA Handler: Memory Constraints

=====

Article Created: 24 April 1989  
Article Last Reviewed: 29 May 1992  
Article Last Updated: 29 May 1992

Note: The following information is applicable only to System 6.0.X running under MultiFinder.

TOPIC -----

What causes the DA Handler to cease functioning occasionally? I am working on a color Macintosh II (with an Apple monitor) with 4 MB RAM, a 40 MB hard drive, and an AppleCD SC and running system software version 6.0.3 and MultiFinder. (I'm also running numerous INITs.) I see the problem when I try to select any DA.

The DA Handler icon flashes in the menu bar, but the system simply returns to the current application. If I try selecting a different application or returning to the Finder, the same thing happens. It also happens under system software versions 6.0.2 and 6.0. The only solution appears to be to restart.

DISCUSSION -----

This situation can occur when you run low on the available MultiFinder memory. If you have enough memory to load the DA Handler, but not enough to run the desk accessory, the desk accessory quits. DA Handler then exits, because there are no desk accessories currently running. Unless the desk accessory reports an error, all you see is the DA Handler launching and then exiting, because there are no loaded desk accessories.

The reason this happens under MultiFinder, and not under Finder, is that DA Handler is an application that is run when a desk accessory is selected from the Apple menu. There is not necessarily enough memory left for it to run, after you have loaded other applications.

In the Finder, desk accessories are loaded into the memory taken by the

currently running application. You can force the same thing in MultiFinder by holding down the Option key when you select the desk accessory.

## Apple IIC Plus: Third-Party Add-On Products

Revised: 6/1/89  
Security: Everyone

Apple IIC Plus: Third-Party Add-On Products

=====

This article last reviewed: 4 April 1989

This article lists four third-party products for the Apple IIC Plus.

### RGB Video Adapter

-----

An RGB video adapter called the "PEACOCK", Model CM2C (RGB Module for the Apple IIC) from Telemac can support both analog and digital RGB. Therefore, let Telemac know what monitor you plan to use when you order the Peacock video adapter.

### Internal 2400 Baud Modem

-----

An internal 2400 baud modem, available from MDIdeas, is called CommLink IIC Plus. The modem uses an internal connector.

### Hard Disk (20MB)

-----

Chinook Technology has a 20Mb hard drive (the CT-20c) that works with the Apple IIC and Apple IIC Plus computers. The drive connects to the disk port on the Apple IIC or Apple IIC Plus.

### Memory Expansion Card

-----

A memory expansion card is available from Applied Engineering. The card uses the memory expansion port inside of the computer. The card can add 1MB of memory to the Apple IIC or Apple IIC Plus.

## A/UX: Name Server Slow BNET Response (8/94)

Revised: 8/25/94  
Security: Everyone

A/UX: Name Server Slow BNET Response (8/94)

Article Created: 6 April 1989  
Article Reviewed/Updated: 24 August 1994

TOPIC -----

This article describes three solutions to slow response of BNET utilities.

DISCUSSION -----

Some users have noticed a slow startup of the BNET utilities "remsh", "rlogin", and even "ping." Suspicions were that this was related to the utilities' failure to make contact with the "named" daemon, thereby causing a timeout before continuing. When this daemon was turned on in "/etc/inittab", it did not appear when the system reached the appropriate run state.

Note that a line in the "inittab" references "/etc/named.boot", a file that does not exist in A/UX as shipped. If you create "/etc/named.boot" as a zero-sized file and restart the system, the "named" daemon runs and networking is much faster. For example, the "ping" program responds almost immediately instead of after five to six seconds. The same applies to "remsh", "rlogin", "rcp", and others.

There are three workarounds for this problem:

### Method 1

-----

1. Choose one system on the network to act as the "name" server.
2. Create a zero-sized file called "/etc/named.boot" on that system.
3. Enable the "named" daemon from within "/etc/inittab".
4. On all other systems on the network, edit the "/etc/resolv.conf" file to include:

```
nameserver <Ethernet address of above machine in dot notation>
```

5. Restart all network utilities that are running.

#### Method 2

-----

1. Turn on the "named" daemon on all systems on the network.
2. Create a zero-sized file called "/etc/named.boot" on each system as previously described.

The second method is slightly less efficient, but may be the better choice because every system on the network has a "name" server and does not have to rely on one system to be present.

#### Method 3

-----

Methods 1 and 2 sound good, but neither includes any "name" server database. You would do well to build a "name" server with real name database into your network.

The reason network activities like "rlogin", "ftp", "remsh" ran slower was because the "name" server was either down or not running, and the libraries (resolver software) that query the domain name server already are built in to A/UX. Because of this, hostname or address queries from a user process are:

- a. First sent to the name server.
- b. If the information is not found, the query is sent to the Yellow Pages.
- c. If the information is not found, the query is sent to the local "/etc/hosts" file.
- d. If the information is not found, the query fails.

For additional information about Name Servers, refer to the A/UX Network System Administration manual section on "Setting Up the Name Server".

## A/UX: How to Use the daiw Command

Revised: 9/28/92  
Security: Everyone

A/UX: How to Use the "daiw" Command

=====

Article Created: 6 April 1989

### Article Change History

-----

08/31/92 - REVIEWED  
• For technical accuracy.

### TOPIC -----

If you have had problems piping to and from "daiw", consider the following command string.

### DISCUSSION -----

It sends the file "args.1" to the ImageWriter II (directly connected to A/UX tty1) without any problem:

```
troff -man -Tiw args.1 | daiw | lp
```

The key point is that you must specify the "-Tiw" option in the "troff" command, so that the output of "troff" can be recognized by the "daiw" command. This assumes that ImageWriter II is the default system printer.

## AppleCD SC: High Sierra CDs Are Accessed like any other Volume

Revised: 6/1/89  
Security: Everyone

AppleCD SC: High Sierra CDs Are Accessed like any other Volume

=====

This article last reviewed: 6 April 1989

Accessing the information on a CD-ROM volume isn't much different than accessing the information on most magnetic disks, whether the CD-ROM discs use HFS (Hierarchical File System) for Macintosh files, ProDOS (Professional Disk Operating System) for Apple II files, or the High Sierra format for either system. Generally, if you know how to work with files and folders (subdirectories) on a hard disk, 3.5-inch disk, or 5.25-inch disk, you know how to work with the files on a CD-ROM under these formats.

High Sierra is a standard way of organizing the information on a CD-ROM. CD-ROM discs that conform to the High Sierra standard can be accessed from a variety of computers. The discs need not be customized for each different computer's operating system. You don't need to know anything about the High Sierra format to use High Sierra CD-ROM discs. You communicate with application programs as you always have.

Likewise, your application sees the CD-ROM disc as any other disk connected to the system. All file I/O calls are standard Macintosh calls. Nothing special needs to be done. For example, if, in your program, you want to read a file from a High Sierra, issue a Read command.

Nevertheless, a custom search engine may be required if the file format is unique and cannot be accessed via another application (like Microsoft Word opening a MacWrite file). If a custom, search engine must be written, using HyperCard might be the most elegant and expedient tool.

Note that there are two specifications of the High Sierra format, High Sierra and ISO 9660. Both are standards that specify a hierarchical volume and file structure for CD-ROM discs.

The High Sierra standard came about when a group of industry representatives met at Del Webb's High Sierra Hotel and Casino in Stateline, Nevada, in late 1985 to cooperatively develop a common logical

format for CD-ROM discs. The result of this series of meetings was a standard known as the "High Sierra" standard. This standard is fully specified in the May 28, 1986, "Working Paper for Information Processing-- Volume File Structure of Compact Read Only Optical Discs for Information Interchange." For obvious reasons, this is known as the "High Sierra paper."

As is the case with all good standards, the world at large wanted to adopt an equivalent standard. The International Standards Organization (ISO) has modified the High Sierra standard by running it through the ISO standardization process. The result is a new international standard, "ISO 9660-- Volume and File Structure of CD-ROM for Information Interchange." This is known as the "ISO 9660 Standard."

Although most existing CD-ROM discs are High Sierra, ISO is the wave of the future, and most future discs will be ISO. Regardless, Apple's driver will enable you to read CD-ROM discs pressed in either format, and wherever we use the term High Sierra in this article, we're referring to both the ISO 9660 and High Sierra, except where explicitly stated differently.

Finally, and as with installing the System software, ALWAYS use the Installer to install the CD-ROM driver. Using the Installer on a Macintosh installs five drivers, including the Apple CD-ROM, ISO 9660, and High Sierra drivers. Copying the Apple CD-ROM icon installs only that file. If you did a "proper" install and cannot access a "High Sierra" disc, that disk might have been created early in the development of optical storage CD-ROM technology and probably didn't follow the standards as they now read.

## LaserWriter II: Duplex Printing and Smudging

Revised: 6/8/89  
Security: Everyone

LaserWriter II: Duplex Printing and Smudging

=====

This article last reviewed: 28 April 1989

When doing duplex printing on a LaserWriter II, many users find a smudge on the top of the second page. It is important to understand why the smudge appears. Most people do duplex printing the following way:

They fill up the paper tray and print out a number of sheets (for example, 50 pages). They then take those 50 sheets from the output tray and put them back into the paper tray with the blank side up. Then, they print the second side on the pages they just put back in the tray. Presto! Duplex two-sided pages.

The problem with printing this way is the pressure that the paper-pickup roller puts on the paper, as it is pulled out of the tray. When printing side two, side one is face down in the paper tray. As each piece of paper is pulled out of the tray, the pickup roller applies pressure to help separate the pieces of paper. As the piece of paper is pulled out of the tray, toner from side one of the page is smeared onto the top of the next piece of paper. The smear is caused by the pressure of the paper-pickup roller as it pushes down on the pieces of paper.

There is no way to prevent this from happening. That is why Apple states in the LaserWriter II owner's manual that duplex printing should be done manually, one sheet at a time.

## MacDraw 1.9.5 and LaserWriter 5.2 Conflict

Revised: 12/6/89  
Security: Everyone

MacDraw 1.9.5 and LaserWriter 5.2 Conflict

=====

This article last reviewed: 28 April 1989

This problem is caused by the combination of MacDraw 1.9.5 (or 1.9.6 from CLARIS) and the LaserWriter 5.2 print drivers. When you rotate a block of text and print to the LaserWriter, you get an ID=2 system error.

This happens with the Macintosh SE, Macintosh Plus, or Macintosh 512Ke, when using the LaserWriter 5.2 drivers. The workaround is to use an older version of the LaserWriter drivers. For the Macintosh 512Ke, this means the LaserWriter 4.0 drivers (versions between 4.0 and 5.2 do not work on a Macintosh 512Ke). For the other machines, choose one of the previous 5.0 levels of the LaserWriter drivers.

## Responder 1.0.1: How to Cure an Unwanted Dialog Box

Revised: 3/1/93  
Security: Everyone

Responder 1.0.1: How to Cure an Unwanted Dialog Box

=====

Article Created: 28 April 1989  
Article Last Reviewed: 10 August 1992  
Article Last Updated: 10 August 1992

TOPIC -----

My copy of Responder 1.0.1 issues a dialog box with the following message:

No Workstation Name Registered. Be sure to install Responder INIT  
in the System Folder.

If you click OK, Inter•Poll continues, and the workstation appears with the  
correct names.

DISCUSSION -----

Responder was updated to version 1.0.1 to fix a problem Inter•Poll had  
identifying the Macintosh IIX. (The Installer for System Software 6.0.3  
automatically installs Responder 1.0.1.) When you use this version with  
the older Inter•Poll 1.0, the problem appears. The fix is to use  
Inter•Poll 1.0.1 with Responder 1.0.1. Also note that this is not the  
current version of Responder. Version 2.0.x is available as of this review.

## LaserWriter IINTX: How to Print from an IBM PC/AT

Revised: 3/4/90  
Security: Everyone

LaserWriter IINTX: How to Print from an IBM PC/AT

=====

This article last reviewed: 28 April 1989

The LaserWriter IINTX manual states that the printer can be set for higher speeds (beyond 9600 bps), but the IBM PC/AT serial port can be set only to 9600 baud on some versions of DOS. Only versions 4.00 and greater of DOS have an option for 19,200 baud (the current upper limit). Although ATs and 386 systems can be programmed to handle faster rates, any application accessing the serial ports through DOS is restricted to DOS Mode Command options.

There are two ways to handle the speed restriction. First, you could buy a LocalTalk PC Card. With it, you can communicate with the printer at 230K bps, instead of 9600.

Second, you could try this method for changing speeds:

- 1) Check the version of DOS being used and the upper limit of its serial port communications.
- 2) Set the PC communications port to 96, N, 8, 1, P to talk to the LaserWriter IINTX.
- 3) Set the LaserWriter DIP switches for serial communications at 9600 baud.
- 4) Send the PostScript Command to the LaserWriter to set the new faster communications speed.
- 5) Reset the PC communications port to the desired speed and parameters using the DOS MODE Command.

The LaserWriter should now be set for the new speed.

Note: It is important to set the handshaking in the LaserWriter to DTR/DSR for DOS if you are not using XON/XOFF. The LaserWriter's default is XON/XOFF, and DOS defaults to DTR/DSR.

## Excel PC Files: How to Prepare Them for the Macintosh

Revised: 7/30/90  
Security: Everyone

Excel PC Files: How to Prepare Them for the Macintosh

=====

This article last reviewed: 20 March 1990

Excel 1.5 for the Macintosh can read only those Excel PC files that are saved in SYLK format. The default format for Excel PC is XLS. The Excel PC user must save a document using the SYLK format before Macintosh Excel can read it. Using AppleShare PC or AFE does not affect the data formats, nor should they in this case. The use of different data formats was a decision made by Microsoft.

However, this is not necessary for Excel 2.2. All versions of Excel now use the same native ("BIFF") file format, and SYLK is not necessary. Users can specify a date system to use 1900 or 1904 via the Calculations, Options dialog box.

## LocalTalk PC Cards and AppleShare PC: Compatible Systems

Revised: 8/28/90  
Security: Everyone

LocalTalk PC Cards and AppleShare PC: Compatible Systems

=====

This article last reviewed: 28 April 1989

The following IBM PC and PC-compatible systems have been tested and found to work with the LocalTalk PC Card and AppleShare PC. The actual working configuration depends on what other cards are in the machine.

- Wyse 286
- Compaq 386, and portable PC
- IBM PC, XT, AT
- PS/2 Model 30
- AT&T 5300

Units that have problems are:

- The Compaq 286 running in 25-MHz mode. This can be changed to run at 8 MHz to work with the LocalTalk PC Card.
- The IBM PC 3270 is not an IBM PC and is not compatible with the LocalTalk PC Card. It is essentially a 3270 workstation whose expanded capabilities include PC operations. This system uses all of the DMA lines and is not compatible with the LocalTalk PC Card.
- Any system that has a bus speed higher than 8 MHz. (Most do not provide a speed-mode to switch to a slower speed, compatible with the standard PC bus timing of 8 MHz.)
- Any system that uses all of the DMA lines.
- All pre-2.0 versions of ATALK.EXE do not support noninterrupt operation. (Anyone running AppleShare PC or anyone who has purchased the LocalTalk PC Card since mid-1988 will have version 2.0 or later, which DOES support

noninterrupt operation and will work in this situation.)

## Apple II Systems: How to Identify them With Inter-Poll

Revised: 3/1/93  
Security: Everyone

Apple II Systems: How to Identify them With Inter-Poll

=====

This article last reviewed: 28 April 1989

This article describes what to do, so that Inter•Poll can identify an Apple IIe or Apple IIGS connected to a network. There are some very specific criteria that must be met:

- The Apple IIGS must have Built-in AppleTalk selected in the Control Panel.
- The Apple IIGS must have the proper port set to "Your Card".
- An Apple IIe with the Workstation Card must be past the Password screen.

The steps for each computer are given below.

### Apple IIGS

-----

For an Apple IIGS to appear in the "Device List" window of Inter•Poll, these steps must be followed:

- 1) Select "Built-in AppleTalk" from the Control Panel. At the same time, set the port that the network is connected to, generally the Printer port, to "Your Card".
- 2) Shut down and restart the system.
- 3) Run Inter•Poll on the Macintosh, or have it running and checking the network.

The Apple IIGS should show up in the Device List window.

Note: Responder is built into the AppleTalk portion of the software for the Apple IIGS.

Apple IIe

-----

- 1) Install the Apple II Workstation Card in slot 7 of the Apple IIe and connect the LocalTalk port to the network.
- 2) Start up the system and log on to a ProDOS server on the network.

Once the system goes past the Password screen, the device shows up in the Device List window of Inter•Poll.

To see if there was something unique about this setup procedure, we considered the Macintosh in a similar environment. If the system is powered up, but no software is loaded (that is, the Macintosh screen shows the disk with a flashing question mark in the middle of the disk), the system is not identifiable from Inter•Poll. At this point, there is no AppleTalk software to respond to the Inter•Poll request. The same is true for an Apple II.

## Macintosh II: Power Supply Pinouts and Power Fail Circuitry

Revised: 7/2/92  
Security: Everyone

Macintosh II: Power Supply Pinouts and Power Fail Circuitry

Article Created: 1 May 1989  
Article Last Reviewed: 29 June 1992  
Article Last Updated:

TOPIC -----

This article discusses the pinouts for the Macintosh II's 15-pin, power connector from the power supply to the motherboard. It also includes information about the Power Fail circuitry, in case you must use an alternative power supply.

DISCUSSION -----

Pinouts

-----

| Pin # | Function |
|-------|----------|
| ----- | -----    |
| 1     | +12V     |
| 2     | +5V      |
| 3     | +5V      |
| 4     | +5V      |
| 5     | +5V      |
| 6     | +5V      |
| 7     | Ground   |
| 8     | Ground   |
| 9     | Ground   |
| 10    | Ground   |
| 11    | Ground   |
| 12    | Ground   |
| 13    | N/C      |
| 14    | -12V     |
| 15    | /PFW     |

The Power Fail circuitry in the Macintosh II power supply senses a level transition from the logic board, initiated by pressing either the button on the back of the machine or the reset key on the ADB keyboard. If this transition does not occur, the power-up sequence does not start. If a steady voltage is applied to the Power Fail signal line into the power supply, the sequence will not start. The power supply must see the transition to begin the power-up cycle. A modified power supply that would power up with a voltage applied steadily, instead of level-shifted, would work in this case.

When the Reset key is pressed, pin 4 (Ground) of the ADB port is connected to pin 2 (PwrOn\*) of the ADB port through a 1N914 diode. This applies a ground to the input of a CMOS chip on the logic board, which turns on a transistor and applies approximately +6VDC to the /PFW signal line (Power Fail Warning\*), pin 15. This level shift on the PFW\* signal line initiates the power-up sequence in the power supply. Once the power supply comes up, +5VDC is applied through another diode to the same line to keep the power supply up.

A power-fail-type circuit is necessary in the current power supply, because there is a thermal sensor on the Macintosh II logic board, which shuts down the system in the event of too-high temperatures. The same circuit shuts off the power supply in response to the Shut Down menu command.

There is also logic in the power supply that generates a Power Fail Warning signal to the system in the event of an AC input voltage failure. Additionally, if AC power is removed from the system, the power fail circuit pulls /PFW low at least 2 ms before the DC outputs fail. There is further information on the operational restrictions of the power fail circuitry in "Designing Cards and Drivers for the Macintosh II and Macintosh SE" from Addison Wesley.

## AppleWorks on 5.25-Inch Disks: Printing to LaserWriter

Revised: 6/8/89  
Security: Everyone

AppleWorks on 5.25-Inch Disks: Printing to LaserWriter

=====

This article last reviewed: 1 May 1989

This article describes how to put together three 5.25-inch disks for printing to a LaserWriter from an Apple II with AppleWorks (releases 2.0 and later). This makes the AppleWorks-LaserWriter connection available when only one or two 5.25-inch disk drives reside on the Apple II system.

### Overview

-----

The process requires these three disks:

- The IWEM.BOOT Disk
- The APPLEWORKS Startup Disk
- The APPLEWORKS Program Disk

Have these disks handy to go through the process described below. The rest of the article describes what to do with each disk, beginning with the IWEM.BOOT disk. The article concludes with listings of the catalogs of the three disks.

### The IWEM.BOOT Disk

-----

For AppleWorks to print to a LaserWriter, you need to download the ImageWriter Emulator (IWEM) to the LaserWriter. To do this, you need the disk labeled: IWEM.BOOT. Follow these steps:

1) Start up the Apple II with the IWEM.BOOT disk. This leaves the user at the Applesoft BASIC prompt.

2) At the prompt, type:

-CHOOSER.II

- 3) Select "LaserWriter" in the top left scroll box.
- 4) In the lower left scroll box, select the zone of the desired LaserWriter.
- 5) In the top right scroll box, select the name of the desired LaserWriter.  
Once you select the LaserWriter in the third box, CHOOSER.II checks for the presence of IWEM. If not already downloaded, it will be downloaded.
- 6) Quit from CHOOSER.II.

This procedure needs to be used each time the LaserWriter is powered off and back on. The power cycle causes IWEM to be purged. Occasionally, the IWEM may be corrupted by other printing sessions, like a Macintosh printing session. If an Apple II workstation attempts to print to the IWEM with no results, try downloading the IWEM again.

#### The APPLEWORKS Startup Disk

-----  
With the IWEM downloaded, the next step is to start up with the APPLEWORKS startup disk and set the desired printer as the default printer for the user. With the disk configured as below, on startup, the Applesoft prompt appears. Follow these steps:

- 1) At the prompt, type:

-CHOOSER.II

This time, CHOOSER.II is used only to select the printer for use by AppleWorks. The APPLEWORKS startup disk assumes the IWEM is downloaded.

- 2) Select the same choices that were selected in the IWEM.BOOT section.  
The selection is written to the APPLEWORKS startup disk. Unless the printer is moved, renamed, or an alternate printer is desired, you do not need to run CHOOSER.II again during future AppleWorks sessions.
- 3) Quit CHOOSER.II.

This presents the following request:

ENTER PREFIX (PRESS "RETURN" TO ACCEPT)

- 4) In response, type:

/APPLEWORKS/

and press RETURN. This displays the request:

ENTER PATHNAME OF NEXT APPLICATION

- 5) In response, type:

## APLWORKS

and press RETURN. This runs the AppleWorks application. AppleWorks requests the APPLEWORKS program disk.

### The APPLEWORKS Program Disk

-----  
Continue the process by following these instructions:

1) Insert the APPLEWORKS program disk. Then press the space bar and RETURN.

2) Once in AppleWorks, select:

#5: Other Activities.

3) Then select:

#7: Specify information about your printer(s)

4) Then select:

#2: Add a printer (maximum of 3)

5) Next select:

#2: Apple ImageWriter

6) Give this ImageWriter driver a name to represent it as the LaserWriter on the network (like "Network LaserWriter").

7) Designate the correct slot -- the slot the Workstation Card is in on an Apple IIe or slot 7 on an Apple IIGS.

8) The default settings on the next screen are correct, therefore, ESCAPE back to the Main Menu. From this point, everything (including control codes for underlining, bold-facing, and so on) functions as though AppleWorks is printing to an ImageWriter.

### Changes To Be Made

-----  
Beyond configuring the disks with the following files, one filename needs to be changed. On the APPLEWORKS startup disk, APLWORKS.SYSTEM needs to be changed to APLWORKS. Leaving the .SYSTEM off allows BASIC.SYSTEM to be the startup application, thus, allowing CHOOSER.II to be run, following startup with the APPLEWORKS startup disk and before running APLWORKS.

There are 21 blocks available on the APPLEWORKS startup disk. It may be possible to create a small menu program to "front end" the APPLEWORKS disk. The menu program is not covered in this document.

The three disk configurations follow:

Async LaserWriter Driver 4.0: Use with LaserPrep 4.0

=====

This article last reviewed: 1 May 1989

If you have had a problem using the Asynchronous LaserWriter Driver, the problem may be the version of your LaserPrep file. The Asynchronous LaserWriter Driver version 4.0 works fine with LaserPrep version 4.0. Other versions of the LaserPrep file, like 5.2, may not print--even though the connection to the LaserWriter is sound.

A successful configuration is:

LaserWriter IINT  
SL Laser 4.0 (Asynchronous LaserWriter Driver)  
LaserPrep 4.0  
Macintosh IIX

Set the baud rate to 9600 in the Chooser. The DIP-switch settings on the LaserWriter IINT had switch 1 up and switch 2 down. Connect the printer to the Macintosh using an 8-to-25-pin cable.

To ensure that the LaserWriter has the proper settings, power on the LaserWriter and look at the test page it prints. The RS-232 9600-baud and RS-422 baud options should be listed on the test page.

## AppleScan 1.0.2 Files: How to Import into Quark XPress

Revised: 6/8/89  
Security: Everyone

AppleScan 1.0.2 Files: How to Import into Quark XPress

=====

This article last reviewed: 1 May 1989

Some users have reported blurry images--both on the screen and on the LaserWriter output--after importing an image created in AppleScan 1.0.2, saved in TIFF format, and imported into Quark XPress 2.0A. The problem appears to be with the way XPress 2.0 interprets TIFF files. You can improve image quality in XPress 2.0 by using grayscale scans and setting the print option, under Page Setup Options, to "Precision Bitmap Alignment".

It appears that Quark XPress does not interpret TIFF images the same way as some other applications, like PageMaker 3.0 and ImageStudio. As with many other types of file format, it's not only the information the format contains, but what the application does with the actual data.

Experimentation revealed that neither PageMaker 3.0 nor ImageStudio displayed the "fuzzy" image problem. Because the problem is with the way the Quark XPress interprets TIFF files, the fix needs to come from Quark.

Macintosh 512K: How to Localize to Spanish

=====

This article last reviewed: 1 May 1989

When trying to localize a Macintosh 512K, some people have reported that the process resulted in the keyboard becoming completely unmapped. That is, keys were interchanged throughout. This can happen when to the standard U.S. Macintosh 512K keyboard (no numeric pad).

The problem results from the U.S. standard keyboard having a different number of keys than the international keyboard. The number of keys affects the mapping. If you are using a Spanish keyboard, select "international keyboard" from the Keyboard CDEV in the Control Panel. Using any Macintosh Plus keyboard also eliminates difficulties.

## AppleShare Server: One Log on per Workstation

Revised: 2/6/90  
Security: Everyone

AppleShare Server: One Log on per Workstation

=====

This article last reviewed: 16 May 1989

Some AppleShare administrators have inquired if there is anyway to partition a server volume into application and work file sections, so that users could mount applications more quickly. In effect, they want users to log on to multiple volumes on a single AppleShare server.

Although this approach could speed up user access time, the problem is that when connecting to an AppleShare File Server, the user logs on to the server itself; not the individual volume. The current implementation of AppleShare File Services does not allow multiple logging on to a server from a single workstation. Allowing multiple connections could create situations that would severely confuse the Finder. To eliminate this as a possibility, each workstation is allowed only one connection to any server.

This article last reviewed: 16 May 1989

To avoid running out of memory in Aristotle while working with more than 500 users, you need to increase the Control Panel setting for the RAM disk from 256K to 512K on the administrator's Apple IIGS. This allows up to 1,000 users in Aristotle. For 1,001 to 1,500 Aristotle users, increase RAM disk size another 256K for a total of 768K in the RAM disk. The Aristotle manual discusses this on page xii:

"By setting 256K minimum RAM (on the RAM disk in an Apple IIGS or with 256K RAM on the expansion card in an Apple IIe), you can manage up to 150 applications on the server and use them to create up to 50 menus for up to 500 users. (Aristotle calls the menus 'classes'.)"

"You can raise these limits by increasing the amount of RAM. With each 256K increment--to a maximum of 1MB--you can manage 150 more applications, 50 more menus, and 500 more students. If you're using an Apple IIGS, however, remember that 256K of the RAM on the expansion card is needed for the workstation to access the network. In fact, more memory may be needed if the user has desk accessories or other memory-resident programs."

Aristotle does not recognize the Apple II Memory Expansion Card (Part number A2B2086) as usable RAM when it is installed in the Apple IIGS. However, Aristotle does recognize this memory card automatically when installed in an Apple IIe.

## Step-Up, Step-Down Transformers: Where to Buy Them (3/94)

Revised: 3/17/94  
Security: Everyone

Step-Up, Step-Down Transformers: Where to Buy Them (3/94)

Article Created: 16 May 1989  
Article Reviewed/Updated: 17 March 1994

TOPIC -----

Where can I purchase a step-up or step-down transformer?

DISCUSSION -----

Generally, the best source for step-up or step-down transformers is the country of destination. Once in the country, a hardware store (as they are known in the U.S.) is the most likely vendor of step-down transformers.

If you prefer to buy in the U.S., stores handling travel goods (luggage and travel accessories) are a possible source, as are ordinary hardware stores and electronic supply stores.

Text Files: The "Lost" Tabs Problem

=====

This article last reviewed: 16 May 1989

If, when saving files as text only (for transfer to MS-DOS applications, for example), you lose tabs, consider the following. Most Macintosh word processing applications save the tabs in the files. Most MS-DOS word processing applications replace tabs with space runs. This is why the MS-DOS files appear to keep their formatting.

Apple File Exchange replaces tabs n spaces if that option is selected in the Macintosh-to-MS-DOS section of the standard text file translator.

## A/UX: Supports HyperCard (9/94)

Revised: 9/21/94  
Security: Everyone

A/UX: Supports HyperCard (9/94)

=====

Article Created: 16 May 1989  
Article Reviewed/Updated: 21 September 1994

TOPIC -----

Many Macintosh applications, including HyperCard, now can run under A/UX.  
As a result, you can develop programs that run under A/UX, such that  
HyperCard can communicate with a user's application programs.

DISCUSSION -----

In general, HyperCard front-end interface XCMDs (external commands) and/or  
XFCNs (external functions) can be written in C or Pascal to communicate  
with a user's application via generic A/UX system calls or A/UX toolbox  
calls. This means that you can port an application from a different UNIX  
platform to A/UX and give it a HyperCard interface.

Oracle Relational DBMS has developed such a HyperCard interface for their  
applications running under A/UX. For more details, search under "Oracle".

## A/UX: How to Specify Nonstandard Macintosh Partition Sizes

Revised: 6/8/89  
Security: Everyone

A/UX: How to Specify Nonstandard Macintosh Partition Sizes

=====

This article last reviewed: 16 May 1989

When running Apple HD SC Setup to partition an A/UX drive, you can specify nonstandard Macintosh partition sizes. However, be aware that the method this article describes should not be used on drives already containing the Root and Usr partition of a standard A/UX drive. Rather, this method is best suited for partitioning secondary volumes for use as additional disk space on an A/UX system.

- 1) In the HD SC Setup 2.0 initial window, select the drive to be partitioned.
- 2) Click on the partition button.

You should see a window with several standard setups, such as 50% Macintosh and 50% A/UX. If one of these configurations fits the your needs, choose that setup.

- 3) If you want something else, click the Custom button.

This presents you with a third window that graphically depicts the partitioning on the hard disk drive.

By clicking and dragging in the gray, nonallocated region, you can create partitions and specify their sizes. You can double-click on a created partition to declare its type (like Macintosh partition).

Your first partition should be a 16K partition of the type "Macintosh Driver".

With the one exception that you can have only one Macintosh partition per hard drive, subsequent partitions can be of any type you desire.

DO NOT PARTITION A HARD DRIVE THAT HAS VALUABLE INFORMATION ON IT. Doing this is the equivalent of initializing the hard disk. You also should not

do this on your boot A/UX volume. If you want to change the partition sizes on your boot A/UX volume that was shipped from Apple, first read the articles in the Tech Info Library on that topic.

## Mixed Environment Network Issues

Revised: 7/30/90  
Security: Everyone

Mixed Environment Network Issues

=====

This article last reviewed: 16 May 1989

This article describes IBM PCs connected via LocalTalk PC Cards via FastPaths to a mixed environment network. Pacer software on the VAX does have the capability to support MS-DOS machines. Although connections are provided for both AppleTalk and Ethernet, the services on an Ethernet direct-connect are a subset of the services for a machine using the LocalTalk PC Card.

Using the LocalTalk PC Card and routing through a Kinetics FastPath, you have complete access to file, terminal, and printing services. Currently, using the supported Ethernet cards for the MS-DOS machine, you have the terminal and printing services, but not the file services.

Ethernet cards currently supported by Pacer on the MS-DOS machines are:

- 3COM Corporation's 501,503,505
- Micom's NI5010,NI5210
- Western Digital's AD03

In the Macintosh world, you have access to the full range of services whether you use Ethernet or LocalTalk.

Alisa Systems supports AppleShare PC using the LocalTalk PC Card connected to a Kinetics FastPath through an AppleTalk network.

With regard to PCSA (Personal Computing Systems Architecture), because this product was specifically designed by DEC to provide file and print services for MS-DOS machines from VAX systems, it should work. Because it is not AppleTalk-based, its presence on the network should have no effect.

Note: This is a theoretical statement, because no reports of problems with both architectures residing on the same network have appeared. The area for potential problems is having AppleTalk and PCSA reside on the same MS-DOS machine and somehow conflicting. The usual concerns of interrupt, DMA, and

driver conflicts would apply in this case.

## LaserWriter: To Avoid Paper Curl, Keep the Paper Dry

Revised: 12/6/89  
Security: Everyone

LaserWriter: To Avoid Paper Curl, Keep the Paper Dry

=====

This article last reviewed: 16 May 1989

Paper coming out of LaserWriters sometimes has curved (almost wrinkled) edges, due to the fusing process acting on damp paper. The problem is usually room humidity, rather than the kind of paper being used. Each type of paper stock has its own blend of fiber or rag content, which affects the curl characteristics, but there are no specific papers that minimize the amount of curl.

The curved or wrinkled edge on almost all paper is normally caused by humidity. The higher the humidity, the more likely a paper stock is to curl. This is due to a rapid, but uneven, drying of the paper stock as it is passed through the heated fuser assembly. This condition can be lessened by storing the paper stock and printing in a dry, humidity-controlled environment. Using a dehumidifier to lower the relative humidity in the room where the printer is located also may lessen the amount of curl.

## SCSI Disk Controller Card with Two Drives Attached

Revised: 6/8/89  
Security: Everyone

SCSI Disk Controller Card with Two Drives Attached

=====

This article last reviewed: 16 May 1989

This article describes the relationship of a SCSI disk controller card, the two hard disks connected to it, and the Macintosh system software. When two hard drives are connected to a controller card, which is connected to the SCSI bus; then accessing, mounting, and arbitration of the hard disks volumes is handled by the disk controller card and not the SCSI bus.

The SCSI address is assigned to the SCSI controller card and sets the priority for the controller card, not the disk drives. So, the system software (Macintosh Operating System) is not addressing the hard drives as SCSI drives but as devices through the SCSI-attached drive controller (the disk drives are talking to the disk controller, not the SCSI bus).

SCSI is a transport medium and does not care what is connected to the SCSI controller, provided the SCSI controller follows the rules for placing information on the SCSI bus. In this case, an INIT is required to tell the SCSI controller how to talk to the two separate hard disks.

## LaserWriter and Word 3.02: Driver 5.1 Versus 5.2

Revised: 12/6/89  
Security: Everyone

LaserWriter and Word 3.02: Driver 5.1 Versus 5.2

=====

This article last reviewed: 16 May 1989

While running Microsoft Word 3.02 and LaserWriter Driver 5.1, some users find that the London and Venice fonts print fine -- but that after they upgrade to LaserWriter Driver 5.2, the fonts print jaggedly.

LaserWriter Driver 5.2 added a feature to allow smoothing on text, graphics, or both. This was different from previous versions where smoothing was a global option. Driver 5.2 provides greater control over the document by letting the user choose among three options.

Venice and London are bitmapped screen fonts and require smoothing when printing. Because Microsoft Word uses its own Page Setup and Print dialogs, it does not properly select the two different smoothing options. It selects smoothing for graphics only.

You can test this by cutting and pasting a PICT of Venice text from MacPaint into Microsoft Word. The picture of the text will be smoothed, but some Venice text in the same Microsoft Word document will not be.

The problem could have been worked around by letting the user select and print with the system's Print dialog. Microsoft Word lets the user display the system dialogs by holding the Shift key when selecting Page Setup or when selecting Print. However, with Microsoft Word, the system's Print dialog command is ignored, and the Microsoft Word dialog must be used.

Products like MacWrite, that use the standard system Print dialogs, smooth correctly with the new driver.

## LaserWriter Plus: How to Print with DOS WordPerfect

Revised: 6/8/89  
Security: Everyone

LaserWriter Plus: How to Print with DOS WordPerfect

=====

This article last reviewed: 16 May 1989

Some people have had problems printing from WordPerfect 5.0 to a LaserWriter Plus. The software is running on a DOS computer with a LocalTalk PC Card installed. The LaserWriter Plus is also on the network.

AppleShare PC or Trading Post from LaserTools is required to print to a LaserWriter directly from a PC application, like WordPerfect 5.0. The application must have its own drivers for either PostScript or Epson printers. If an Epson driver is not available, a text printer driver will work.

The software that comes with the LocalTalk PC Card is a set of tools and utilities. These are not meant to provide the print services, like printing from an application, provided in AppleShare PC.

The configuration steps for printing with these products are well-documented in their respective manuals and should present no problems. The actual printing is up to the word processor. The steps necessary to print, once the LocalTalk software is installed, are based solely on the application that created the document. If there are problems after the LaserWriter has been correctly connected from the AppleShare PC DA, and the application has been set to use its PostScript driver, usually the problem is due to the implementation of the particular driver belonging to the application.

Consider the following example. If AppleShare PC has been configured to use the LPT1 port and is set for PostScript, the application only needs to be configured to use its PostScript driver and to print to the LPT1 port. All printing commands, options, and steps are the application's at that point. In fact, the LocalTalk PC Card and AppleShare PC are only passing along the information to the LaserWriter. They are not interfering with the print commands at all.

If AppleShare PC has been configured to use the LPT1 port and is set for

Epson emulation, the application only needs to be configured to use its Epson driver and, once again, to print to the LPT1 port. In this case, the PC will probably print slowly, because AppleShare PC is intercepting the Epson printer commands generated by the application's Epson driver and converting them to PostScript before passing it to the LaserWriter.

Make sure you know how to connect the LaserWriter to an LPT printer port with AppleShare PC and how to select the appropriate PostScript driver for a LaserWriter and an LPT port. The process is the same from the application side whether directly connected or not. The only difference is that the usual DOS configuration of a PC communications port is replaced with the AppleShare PC configuration. The AppleShare PC only needs to be configured once, because AppleShare PC can be set to connect to the printer on each startup.

WordPerfect 5.0 has been successfully tested with an IBM PC and AppleShare PC. The only exception is with pre-REV 47 LaserWriter boards. This is because the WordPerfect PostScript driver takes advantage of some optimized PostScript routines found in the LaserWriter Plus and later PostScript LaserWriters (REV 47 ROMs) and is not compatible with the earlier ROMs.

The steps for printing from WordPerfect 5.0 are as follows:

- 1) Install the LocalTalk PC Card and connect to the desired LaserWriter.
- 2) Install AppleShare PC.
- 3) Execute the DA application or use the hot key.
- 4) Connect the LaserWriter.
- 5) Choose PostScript for the printing mode.
- 6) Exit from the DA.

This is where the WordPerfect application takes over:

- 1) Execute WordPerfect.
- 2) When ready to print, press Shift F7.
- 3) Select S for select printer.
- 4) Type 3 for Edit printer connection.
- 5) Type 2 for Additional Printers.
- 6) Move the highlighted cursor to the Apple LaserWriter Plus driver.
- 7) Press Return.

The Fonts should be loaded into the driver.

- 8) Press Return after selecting the Font options when they appear.
- 9) Press Return again after selecting the printer name and PORT connection.
- 10) Press Return after selecting the name of the printer connection from above.
- 11) Type 1 for full document print.

There are several intermediary steps depending on what options are chosen, but these are the basics. The WordPerfect setup has nothing to do with the connection, except choosing THEIR LaserWriter Plus Driver and selecting the same port as configured in the AppleShare PC DA. The same steps are true

when selecting another type of printer driver.

The default port for WordPerfect is LPT1. The default Port in AppleShare PC is LPT3. It does not matter which one is changed as long as both are the same.

## LaserWriter IISC: Uses QuickDraw, Not PostScript

Revised: 6/8/89  
Security: Everyone

LaserWriter IISC: Uses QuickDraw, Not PostScript

=====

This article last reviewed: 16 May 1989

Printing to a LaserWriter IISC sometimes seems to takes a long time (for example, one customer reported that from Excel the average is about 4 minutes per page). This relative slowness is a result of the printing process used by the LaserWriter IISC. Rather than interpreting PostScript commands (as is done by the LaserWriter IINT and LaserWriter IINTX), the LaserWriter IISC creates QuickDraw to a Raster image. This is essentially a bitmap of the screen image. QuickDraw printing is much slower than PostScript, and no speed increases are available.

## Apple Data Modem 2400: Q & A from LAN Minds Training

Revised: 7/26/93  
Security: Everyone

Apple Data Modem 2400: Q & A from LAN Minds Training

=====

Article Created: 8 June 1989  
Article Reviewed/Updated: 22 July 1993

This article is a question and answer session concerning the Apple Data Modem 2400. It takes care of questions the Technical Resources LAN Minds training left unanswered.

1) What is the maximum speed through the pass-through port?

The maximum speed is 57.6kbps. This is gated by the Serial Communications Controller (SCC) chip.

2) Are there any compatibility problems with Shiva's NetSerial?

There shouldn't be, if the NetSerial package supports standard modems. However, we are checking with the test

3) Can Apple post a list of other MNP modems, and state whether they are compatible with these modems?

This modem is compatible with all MNP level 1-9 modems. It will only negotiate a 4 or lower link, no matter what is calling. MNP is a standard that clearly defines handshakes and data transmission. It is compatible with Relay Technology (formerly MicroCom), Telebit, and Codex, the major MNP vendors. In this case, the product should be compatible with anyone who correctly implements the standard.

4) Can the modem be used with Hypercard?

Yes, serial XCMDs and the modem commands in HyperCard work.

5) Direction: In the LAN Minds' writeup on the Apple Data Modem 2400

(Volume 2, Section 18), there is reference to the Microcom Network Protocol (MNP) classes. In Class 1, states that this protocol defines half-duplex transmission. There is also a statement to the effect that because the modem lacks the Clear to Send (CTS) and Request to Send (RTS) lines, the modem does not support Class 1. This reason was incorrect.

The MNP specifies a half and full-duplex protocol, but not hardware half and full duplex. These are two different uses of the same words. The hardware half and full duplex defines the modulation mechanism for communication between modems. MNP half and full-duplex defines the communication protocol on a modem-to-modem basis (not on computer-to-modem basis as implied in the writeup).

In class 1, this protocol specifies that an 8-byte block is sent out and that the modem waits for a response before sending the next block. Class 2 permits four successive 8-byte blocks to be sent out. On the receiving end, an acknowledgement is sent as each block is received. When the originating modem gets an acknowledgement it adds the next block to the list to be sent. Thus, there are always be four blocks in a queue waiting or being transmitted. With class 2, if a block is not full, it will wait until it is full.

Class 1 alone is not supported in the Apple Data Modem 2400. Although the design does not support this level only, it is the basis for the other classes.

Also note that half and full duplex is also interchangeably used with the echo function set in the terminal software. This usage of the word refers to the echoing of character from the modem back to the host computer.

## MacX: High Level X Display Server Description (1/95)

Revised: 1/30/95  
Security: Everyone

MacX: High Level X Display Server Description (1/95)

=====

Article Created: 8 June 1989  
Article Reviewed/Updated: 30 January 1995

TOPIC -----

This article provides a high level X display server description.

DISCUSSION -----

MacX is an X display server for the Macintosh Operating System. MacX 1.2 complies with the X Window System, Version 11, Release 4. It also supports failure of individual client requests (as opposed to the whole server) and the inclusion of DECW\$CURSOR and DECW\$SESSION fonts.

MacX lets multiple X11-compliant clients share the Macintosh display. Unlike other X display servers, MacX has many built-in functionality with the X display server. These function include:

- X window manager with Macintosh Finder-like appearance
- Font manager
- Color namer
- Remote command

The font manager handles the cataloging of X (Adobe's Bitmap Distribution Format - BDF), DECwindows and Macintosh fonts. BDF fonts, the format used by the X Consortium to distribute fonts, needs to be compiled before they can be used by MacX. The font manager has a built-in font complier.

Also, the font manager lets you assign alias names to fonts. This particularly useful with the X fonts, because the X font naming convention is quite lengthy. This allows for a convenient means for referencing fonts.

The color namer lets you assign a name to a color selected via the standard color wheel dialog box (the same one from Control Panel). This alleviates the need for a user to define a color with RGB values. It also uses an easy-to-remember name to reference a particular color.

From MacX, remote commands can be sent to hosts on the network. Remote commands issued from MacX can be saved to a document and used again at a later time. A host informational status window is provided to find out status about commands requested via MacX.

In addition, MacX has two operating modes, rooted or rootless. Each mode has a color and monochrome support. While in the rooted mode, another X window manager can be requested to manage client windows attached to these rooted windows. These rooted windows can be defined to be up to 2048 by 2048 pixels in size. In the rootless mode, the client windows have a Macintosh Finder "look and feel" like a Macintosh title bar with a close (kill client) box. The client windows appear to be like any other window on the desktop.

Because the Macintosh has only a single button mouse, the three-button mouse, which is very popular in the X world, is mapped to the arrow keys on the keyboard. Arrow keys perform the arrow function and option-arrow perform a three-button mouse operation or visa versa.

MacX connects to the network via the Macintosh Communications Toolbox. MacX supports TCP/IP, ADSP and TSSNet (DECnet) tools.

## MacX: Q & A From LAN Minds Training (4/93)

Revised: 4/23/93  
Security: Everyone

MacX: Q & A From LAN Minds Training (4/93)

=====

Article Created: 8 June 1989

### Article Change History

-----

04/20/93 - UPDATED

- To include MacX 1.2 information.

### TOPIC -----

This article is a question and answer session concerning MacX. It takes care of questions the Technical Resources LAN Minds training left unanswered.

### DISCUSSION -----

- 1) What is the difference between the MacX X display server versus other X display servers? In particular, what are the feature difference?

Although it is a display server, MacX has X window-manager capabilities that provided Macintosh-like user interface. It has many user-friendly interfaces like font and color managers to make it easier to work with X.

MacX has two modes, rooted and rootless windows. Effectively, these two modes can provide four displays. With rooted windows, other X window managers can be launched to handle the client windows within the rooted window. The rootless windows provide Macintosh-like windows that appear on the desktop.

Because MacX runs on the Macintosh hardware platform, all the other Macintosh applications are also available for use. MacX is MultiFinder-compatible.

The key factors in comparing X display servers are the following: screen size and resolution, type and speed of the processor, the availability of a graphics coprocessor, RAM configuration and expandability, color support, and price.

- 2) It seems like the MacX is more than just an X display server. What client functions are built in?

As far as client-like function, Finder-like X window manager, and a utility to show samples of a font type are built into MacX. Cut and Paste on the Macintosh side is already implemented as part of the Macintosh. MacX also has a color namer and the remote command startup facility. The "rootless" style and the ability to support display area larger than that present on the physical screen are also extensions to the normal functionality.

- 3) Are there any third parties developing the three-button mouse for the Macintosh?

To locate a vendor's address and phone number, use the vendor name as a search string. These companies manufacture compatible three-button input devices:

- Logitech, Inc.
  - MouseMan (mouse)
  - TrackMan (trackball)Both are compatible with Macintosh OS, A/UX, and MacX
- Mouse Systems Corp.
  - A3 Mouse
  - A3 TrackballBoth are compatible with Macintosh OS, A/UX, and MacX
- Advanced Gravis Computer Technology Ltd.
  - Gravis SuperMouseCompatible with Macintosh OS, A/UX, MacX, X11, and SoftPC

- 4) Is there any capability to cut and paste graphic information?

Cut and paste of graphic information is available. It probably will be a simple cut and paste of pixmaps -- not object-oriented graphics (like MacDraw) -- only bits that are rendered already (like MacPaint). Refer to the MacX 1.2 Manual.

- 5) An engineer indicated some X window managers are hardware dependent. Are there X window managers that will not work with MacX?

We are not aware of any X window managers that are hardware dependent. We don't know of any window managers that will not work with MacX. MacX

has been used with uwm (Universal Window Manager), twm (Tom's window manager), mwm (Motif Window Manager), and olwm (Open Look Window Manager).

- 6) What is the relationship between DECWindows and MacX? How do they work together? What do you need to make them work together?

MacX is an X11 display server, just like any other X display server. DECWindows is a name for a broad range of X software. It includes a display server for DEC's Ultrix (UNIX), VAX/VMS and MS-DOS machines, client applications, and programming tools.

If DECWindows can interoperate with X11-conformant servers, it can interoperate with MacX. MacX is shipped as a part of the VAX/VMS Services for Macintosh product and includes the completely DECWindows font set, but this is not required to run DECWindows clients. If the DECWindows fonts are not present, either font name aliases or changes on the VAX side can be easily made to permit MacX to work with DECWindows anyway.

You don't need anything special to make them work together, other than the possible requirement for font aliases listed above.

There is one known compatibility problem. It appears the most significant bit is reversed in the client used to display the Digital logo. When shown on MacX, eight-bit bands of information is reversed. The exact problem has not been identified in either the MacX or DEC client.

- 7) Will the ability of extending the X Window standard display server and clients create compatibility problems in the field?

The X11 protocol permits clients to ask whether the server supports particular extensions by name. Properly written clients might fall back on a different strategy if extensions they normally use don't exist. But yes, there can be "compatibility" problems, if this is not the case.

- 8) Does the toolkit that MacX uses conform to a standard toolkit like Xtk?

This question is based on a misunderstanding. The Xtk code runs on the CLIENT side. It specifies a way of programming user interfaces in the CLIENT program. MacX (or any other X11 server) simply draws what the client asks for. There is no "toolkit" in MacX.

- 9) Is there any graphic model being used in MacX (like Display Postscript)?

The name is "The X Window System" according to "X protocol version 11". MacX conforms completely to these specifications, except as outlined in the appendixes of the manual. (In some very small ways, MacX diverges

slightly.)

10) Is it possible to change the window types available in the Set Window Type menu?

No. Only the five show can be selected. "Client Specified" means the client specifies one of the ones shown (1 through 5).

11) What are the official names of the X Window System?

The official names of the software from MIT is:

- X
- X Window System
- X Version 11
- X Window System Version 11
- X11

Note: Phrases like "X.11", "X-11", and "X-Windows" are explicitly excluded and should NOT be used to describe the X Window System.

## X Window System: A Description

Revised: 6/12/89  
Security: Everyone

X Window System: A Description

=====

This article last reviewed: 8 June 1989

### BACKGROUND

-----

The X Window System (or X) evolved out of a project (Athena) at the Massachusetts Institute of Technology (MIT). The goal of this project was to use the networked graphic workstation as a teaching aid. With the support of some corporate sponsors, notably Digital Equipment Corporation (DEC), the X has become the de-facto graphics and windowing standard.

X is being developed by a consortium of industry and academic members under the auspices of MIT. Apple is a member of the X Consortium.

X's principal benefit is that it allows workstation interoperability between different vendors, regardless of hardware platform and operating system.

### X WINDOW SYSTEM ARCHITECTURE

-----

The X Window System is based on the server-client model. The server is a shared display. This display comprises a keyboard, pointing device like a mouse, and multiple screens (monitors). The display server can support simultaneously multiple number of clients from different hosts.

Unlike other server-client models like AppleShare, the location of the server is reversed (from the user's perspective). In AppleShare, the server is accessed by the user's workstation over the network. In X, the user works at the server (where the information is being shown on the shared display).

Also, the server only provides the mechanism for information to be draw in window. "Policy" is how a user interacts with the windows like moving, resizing, and iconifying them. The policy ("look and feel") is handled by a client application called the X window manager. This separation of the

policy functionality lets X avoid standardizing on any particular user interface.

X clients are applications. X clients are designed, so they can run locally with the server (if the computer supports preemptive multitasking) or remotely over a network.

These clients are designed in a layered fashion. Clients access an X toolkit. The toolkit is a collection of graphical procedures which generate object like scroll bars and buttons. There are a variety of toolkits available. In turn, the procedures in the X toolkit call a standard set of primitive graphics functions stored in a library called Xlib. These Xlib functions provide operations such as drawing a rectangle or filling a box. Xlib functions generate X protocol streams.

X protocol is a low-level protocol used to connect servers and clients together. This protocol which makes it possible for different vendors to communicate with a standard language. X protocol also permits network transparency. Like the AppleTalk protocols stack, by changing the transport layers, X can be run over a variety of physical networking standards.

Portability was a major design criteria for X. X Window System was originally developed in the UNIX and C environment. With it's layered design, it was very easy to transport X to other systems. With Xlib now available in FORTRAN, MODULA-2, PASCAL and Ada, many other environments develop X applications.

## REFERENCE

-----  
There is a growing number of books on the X Window System. In addition, documentation can be obtained directly from the X Consortium at the MIT Software Center. Search the Tech Info Library under "MIT Software Center" for more information:

## The SMB File Transfer Utility: General Information

Revised: 10/4/89  
Security: Everyone

The SMB File Transfer Utility: General Information

=====

This article last reviewed: 12 June 1989

The SMB File Transfer Utility allows a Macintosh II to transfer files between an SMB server (named for the SMB (Server Message Blocks) protocol) and a Macintosh II over a Token Ring network. Apple File Exchange (AFE), translators (MS-DOS to/from Macintosh), and the Apple TokenTalk NB card are used to do this.

Before installing the SMB File Transfer Utility, you must install the TokenTalk NB card and its associated software. Refer to the TokenTalk NB User's Guide for information on installation.

The Installer is used to set up the SMB File Transfer Utility. System resource version 6.0.3 is required and is included. Follow normal procedures to install the software. AFE is also needed to run the SMB File Transfer Utility. If AFE is not already present, install it, along with any translators that you may want, all in the same folder (the proper version of AFE is also included).

The SMB File Transfer Utility runs under AFE, supplying a desk accessory, called SMB Servers, to connect to an SMB server. To use the SMB File Transfer Utility, open AFE. This makes the SMB Servers DA available. The next step is to open the DA, which supplies a dialog box. This dialog box features four buttons:

- Connect--connects to an SMB volume that has already been added.
- Add--adds an SMB volume name to the volume list.
- Remove--removes an SMB volume name from the volume list.
- Disconnect--disconnects from an SMB volume that is already connected.

The dialog box also contains three windows:

- Workstation Name displays the name of your workstation.
- Select an SMB Volume displays a listing of the SMB volumes you have already added.
- Connected SMB Volumes displays a listing of the volumes already connected.

You must first choose a Workstation Name, which identifies your Macintosh II to the network administrator. The Workstation Name does not have to be set up on the server side. It is an optional security feature. Using the Add and Remove buttons, you can maintain a list of volumes available on the network. Unlike AppleShare, the SMB File Transfer Utility requires you to know the names of any servers that are going to be accessed. To access a volume, you must first mount it using the Connect button (Disconnect will sever a volume connection, as will leaving AFE). Once a volume is connected, you can use AFE to transfer files between a local volume and the connected server, or between two different connected server volumes. Up to six volumes on any combination of servers can be open at one time.

The SMB File Transfer Utility and the following documentation are bundled with the TokenTalk NB card.

- Apple SMB File Transfer Utility User's Guide. This guide includes an AFE usage section and the Appendix contains a list of translators available for AFE. (AFE is documented in the Macintosh Utilities User's Guide.)
- TokenTalk NB User's Guide.

## Apple Serial NB Card: General Information (6/95)

Revised: 6/6/95  
Security: Everyone

Apple Serial NB Card: General Information (6/95)

Article Created: 12 June 1989  
Article Reviewed/Updated: 6 June 1995

TOPIC -----

This article provides general information on the Apple Serial NB card.

DISCUSSION -----

The Apple Serial NB card is an intelligent NuBus card that uses Apple's Macintosh Coprocessor Platform (MCP) architecture. It provides additional communications and processing capabilities to a Macintosh computer.

The card includes a Motorola 68000 processor operating at 10 megahertz and 512 kilobytes of random access memory (RAM), which is expandable to 1MB. Software for the MCP consists of MCP/OS, Apple IPC, and support software. MCP/OS and Apple IPC supports a multitasking distributed operating environment for communications and other real-time services on the same card.

The card uses two Zilog SCC chips to support a total of four serial ports. A 62-pin connector on the back of the card breaks the electrical signalling into the respective ports. These ports can be configured to operate as four RS-232-C ports, or as two higher speed ports (such as V.35) and two RS-232-C ports. The RS-232-C ports can operate at speeds up to 19.2 kilobits per second (Kbps). The higher speed ports are DMA-backed and can operate at speeds up to 64 Kbps. Cabling for this card comes in two flavors: the Hydra cable, which provides four RS-232-C connectors (M0128LL/A), and the V.35 cable (M0127LL/A), which provides one V.35 port and one RS-232-C port.

The Apple Serial NB card can support more than one networking protocol because of its multitasking operating system and multiple independent ports. The card can be installed in a Macintosh II serving as a gateway to other networks, such as SNA with the SDLC protocol and X.25 with the HDLC protocol. This card is designed to be a platform for various serial communications applications (initially, MacAPPC and MacX25). The features and capabilities of the card correspond to the AST serial communications card, which has been available for

some time and which also can run the MacAPPC and MacX25 software. The memory expansion option was implemented to allow MacAPPC to serve a large number of users and to provide enough memory for a customer to run multiple applications.

The two cabling options were designed with MacAPPC and MacX25 in mind. The cables are available for purchase separately. Future software developed for the card may require new cables to be built.

The following documents contain details about the Apple Serial NB card or its technology:

- Apple Serial NB Card Installation Guide (included with the card)
- Apple Macintosh Coprocessor Platform Developer's Guide (available through APDA)

Article Change History:

06 Jun 1995 - Corrected V.35 cable part number.

17 Feb 1995 - Corrected typo.

## Apple Scanner and Macintosh Start-Up Problems

Revised: 7/28/89  
Security: Everyone

Apple Scanner and Macintosh Start-Up Problems

=====

This article last reviewed: 14 June 1989

PROBLEM: The Apple Scanner and sometimes other SCSI devices when used with Macintosh IIcx, Macintosh IIx or Macintosh SE/30 sometimes do not allow the Macintosh to start up or system bombs may occur during SCSI data transfer from the scanner.

CURE: There are several ways to solve this problem: rearrange the SCSI chain, add a second terminator, add or remove a SCSI extension cable or remove the terminator from the chain. If there are other SCSI devices in the chain, change their positions within the chain. For example if the SCSI chain looks like this:

Macintosh -----Scanner-----HD40SC-----  
Terminator

Rearrange the chain like this:

Macintosh -----HD40SC-----Scanner-----  
Terminator

If there are more devices changing the scanner location with another SCSI device should take care of the problem.

## Macintosh: Serial Port Configurations for Nonstandard Baud Rates

Revised: 7/28/89  
Security: Everyone

Macintosh: Serial Port Configurations for Nonstandard Baud Rates

=====

This article last reviewed: 9 June 1989

Inside Macintosh, Volume II (pages 250-251) tells how to configure for eleven baud rates: 300, 600, 1200, 1800, 2400, 3600, 4800, 7200, 9600, 19200, and 57600.

Here's how to configure for other values.

For example, to obtain 38,400 baud rate on your serial port, the correct value to pass to SerReset is "1" for the baud rate constant.

Note that you can specify a given baud rate by making the serial driver control call with a control (csCode) of 13. The driver will return the closest baud rate that the serial driver will generate. This is documented in Inside Macintosh, Vol. II-254.

Some trivia:

The formula for figuring out the SerConfig baud rate constants is:

$$\text{Baud Rate Constant} = \frac{114709}{\text{Baud Rate}} - 2.0$$

For example, the baud rate constant for 9600 baud is:

$$\text{Baud Rate Constant} = \frac{114709}{9600} - 2.0 = 11.949 - 2.0 = 9.949 = 10$$

The 114709 figure comes from the SCC clock (3.670702 MHz) which comes from the system clock (15.6672 MHz), but doesn't divide down evenly because of the timing PALs (in fact  $3.670702 = 15667200 / 4 * 15/16$ , where the 15/16 is due to PAL timing). For the MacXL (Lisa), use 115200 instead of 114709.

Similarly, you can do a reverse calculation and find the baud rate, given a constant. Reversing the formula, you get:

$$\text{Baud Rate} = \frac{114709}{\text{Baud Rate Constant} + 2.0}$$

So, using the constant 10 (for 9600 baud), the formula gives

$$\text{Baud Rate} = \frac{114709}{10 + 2.0} = 9559.083$$

This isn't exactly 9600 baud. In fact the error percentage is:

$$1.0 - \frac{9559.083}{9600} = 1.0 - 0.996 = 0.426\%$$

If you try this with 38400, you get:

$$\text{Baud Rate Constant} = \frac{114709}{38400} - 2.0 = 2.987 - 2.0 = 0.987 = 1,$$

a baud rate of:

$$\text{Baud Rate} = \frac{114709}{\text{Baud Rate Constant} + 2.0} = 38236.333,$$

and an error percentage of:

$$1.0 - \frac{38236.333}{38400} = 1.0 - 0.996 = 0.426\%$$

## AppleShare PC 2.0 (Discontinued)

Revised: 3/25/94  
Security: Everyone

AppleShare PC 2.0 (Discontinued)

=====

Article Created: 28 July 1989  
Article Reviewed/Updated: 25 March 1994

NOTE: AppleShare PC was discontinued by Apple in 1990.

### Overview

-----

AppleShare PC 2.0 is a revision of the existing AppleShare PC 1.2. This software allows MS-DOS machines to act as clients to an AppleShare File Server and to access print services provided on an AppleTalk network.

### New features

-----

AppleShare PC 2.0 provides the same functionality as earlier versions with the addition of support for AppleTalk Phase 2 protocols and the Open Datalink Interface (ODI), which was designed by Novell in conjunction with Apple. ODI is a set of specifications that allow a separation between the network protocol stacks and the device drivers. These drivers are specific to a particular network medium such as LocalTalk, Ethernet, or Token Ring. In the past, with versions of AppleShare PC 1.1 and earlier, the network protocol stacks and Link Access Protocol drivers were integral. They could not be separated to provide support for third-party network cards and consequently, only the Apple LocalTalk card worked with AppleShare PC. Version 2.0 includes drivers for:

- 3COM's EtherLink II and EtherLink/MC (Microchannel)
- Three IBM 802.2 Token Ring cards
- Daystar's Microchannel LocalTalk Card
- Apple's LocalTalk card

Only those cards listed above have drivers included with AppleShare PC 2.0. Because Novell has published the ODI specifications, drivers for other network cards, such as Microchannel LocalTalk cards, will be provided by third-party vendors.

The AppleShare PC 2.0 installation program also has the ability to load

only AppleShare File Services, only AppleShare Print Services, or both. This is useful when memory use is restricted. AppleShare PC 2.0 now includes additional batch files, which allow dynamic loading and removal of AppleShare File Services and Print Services.

#### Open Datalink Interface

Novell's Open Datalink Interface (previously called MLI/MPI) provides support for any number of network protocols (such as AppleTalk, AppleTalk Address Resolution, IPX, Netware, TCP/IP) working with any type of network media interface. This gives the user the ability to add or change network protocols without having to change network interface cards.

ODI also provides major benefits to third party developers by allowing them to write only one device driver for their card. The driver will then work with any set of network protocols. Because the AppleTalk Phase 2 protocol stack is being written to the ODI specification, AppleTalk services, such as the AppleTalk Filing Protocols and AppleTalk Print Access Protocols, can be used over any network card that has a device driver written to the ODI specification.

Communications between the protocol stack drivers (currently referred to as the MPI interface) and the network card drivers (currently referred to as the MLI interface) are handled by the Link Support Layer (LSL). Under the ODI specification, data packets need only be directed to the LSL instead of a specified device driver. The LSL then acts as a "postal service," which correctly directs inbound and outbound packets to the specified stacks and drivers. This means the system is responsible only for directing data packets to the LSL instead of the full distance to the protocol stack or some specified driver.

#### Installation

The AppleShare PC installation software has been improved. In version 2.0, each step of the installation has on-screen instructions and is much more flexible in its options. For example, you can now select which services are to be loaded into memory. You can choose file services only, print services only, or both. You can also choose to load only the MLI drivers for certain network cards or to load the MLI drivers and the AppleTalk protocol stack.

When loading the selected modules into AppleShare PC 2.0, you can now calculate the amount of memory that will be used based on the options installed. Below is a table describing the memory requirements:

|                                        |            |
|----------------------------------------|------------|
| File and Print Services                | 117 - 126K |
| File Services only                     | 91 - 100K  |
| Print Services only                    | 62 - 71K   |
| AppleTalk and MLI driver(s) only       | 49 - 58K   |
| MLI driver(s) only                     | 13 - 22K   |
| Add 57K to make the DA memory resident |            |
| Add 6 - 15K per additional MLI driver  |            |

The AppleShare PC 2.0 installation program presents a list of cards that

have MLI drivers resident in the AppleShare PC installation directory. You can choose one or more MLI drivers corresponding to the cards installed. For some cards, such as third party Ethernet and Token Ring cards, additional questions will be presented in the installation, such as the settings of the card's DIP switches, DMA interrupt addresses, and IRQ settings. Refer to the card's user guide for the proper setting of these switches and addresses.

If multiple network cards are installed in a machine, the installer will ask which MLI driver to use as the default. To change MLI drivers after the default has been loaded, use the USE option of ANET.

#### New ANET Features

-----  
The ANET command interpreter, which performs functions similar to the DA through the command line and batch files, has several new subcommands. These new subcommands now support AppleTalk Phase 2 and ODI features. Below is the syntax of the four new ANET subcommands.

CONFIGURATION allows you to view configuration information about MPI stacks and MLI drivers.

CONFIGURATION [[ALL [STACKS | MLIDS]] | MPIstackname | MLIDname ]

DEFAULT sets a new MLID as the default when AppleShare PC is started. DEFAULT with no parameters displays the current default MLID.

DEFAULT [MLIDname]

LIST displays all Apple TSRs, MPI stacks, and MLI drivers.

LIST [TSRS | STACKS | MLIDS | ALL]

REMOVE removes most Apple TSRs, MPI stacks, and MLI drivers from memory.

REMOVE ALL | modulename [modulename]...

STATISTICS allows you to view statistics from the Link Support Layer, MPI stacks, and MLI drivers.

STATISTICS [LSL | MPIstackname | MLIDname ]

STATISTICS ALL [STACKS | MLIDS]

USE allows you to change the currently loaded MLID, card number (if an MLID supports more than one card in a machine), zone name, and/or suggested network number.

USE MLIDname [#cardnumber] [Z(zonename)] [H(netnumber)]

#### AppleTalk Phase 2

-----  
AppleTalk Phase 2 is required for AppleShare PC 2.0 environments using Ethernet or Token Ring networks. For AppleTalk networks using only LocalTalk cabling, AppleTalk Phase 1 protocols are used.

One consideration to be taken into account when using AppleShare PC 2.0 in an AppleTalk Phase 2 environment: if an MS-DOS client is on a network with no routers and a router then comes up on the network, the AppleShare PC 2.0 client may be required to restart their machine. This is because on a

Phase 2 network the zone and network number can be defined by the node if no routers are present. When the router appears on the network, it will define the zone and network numbers, which may conflict with those defined by the node (i.e. the AppleShare PC 2.0 client).

#### Compatibility

-----  
AppleShare PC 2.0 is compatible with MS-DOS 4.0, and all MS-DOS programs which were compatible with AppleShare PC 1.x.

A/UX X11: How To Cut and Paste (6/93)

Article Created: 30 May 1989  
Article Reviewed/Updated: 25 June 1993

TOPIC -----

In A/UX X11 window System Release 4 under the "xterm" client application, you can click the mouse button to save text into the cut buffer.

DISCUSSION -----

Here's how to cut and paste:

- 1) To cut text, use a click and drag technique as you do in the Macintosh OS. That is, you move the pointer to the beginning of text to be selected, press and hold the button, drag the mouse through the text to be included, and release the button. The selected text is highlighted and saved in the global cut buffer.
- 2) Once you have cut the desired text, move the mouse pointer to where the cut buffer is to be pasted.
- 3) Press the "left arrow" key to insert (paste) the text from the cut buffer as keyboard input in the xterm's window.

For more information, refer to the xterm(1) manual page, "pointer usage" paragraph. Release 3 users can also read appropriate sections of the "X11 User's Guide for A/UX."

A/UX 1.1: Limited Support for the Apple SuperDrive (9/94)

=====

Article Created: 28 July 1989  
Article Last Reviewed: 21 September 1994

TOPIC -----

Does A/UX 1.1 support the Apple SuperDrive (formerly Apple FDHD)?

DISCUSSION -----

No. Under A/UX 1.1, the SuperDrive functions as an 800K floppy disk drive; it cannot take advantage of the 1.4MB floppy disk drive supported under Macintosh OS at this time.

A/UX version 3.0 does indeed support the SuperDrive. This is the only solution.

Macintosh SE: Hyphens and Asterisks Overwrite Icon Names

=====

Article Created: 5 April 1989  
Article Last Reviewed: 6 August 1992  
Article Last Updated:

TOPIC -----

When I select a Finder icon, the name under the icon is selected and automatically written over with hyphens (-) or asterisks (\*). The name field continues to fill until it reaches the maximum number of characters for the name field. A blinking cursor sits at the rightmost character.

DISCUSSION -----

The problem can exist in any of these areas:

- Badly-formed asterisk and hyphen keycaps on the numeric keypad
- Keyboard or ADB hardware
- A faulty logic board

To diagnosis the problem, follow the above order.

First, check the hyphen or asterick keys on the numeric keypad. You may find them partially depressed. This occurs because of a tiny plastic protrusion left on some keycaps after manufacturing. Some troubleshooters have found this protrusion catching on the case just enough to produce characters, but not enough to be noticed at a glance. The fix is easy; remove the keycap(s) and shave off the plastic protrusion.

Second, if nothing is wrong with the keycaps, try changing the keyboard and cable.

Third, if the problem remains, change the logic board.

## Network Termination Issues: The Terminator (Part 1 of 2)

Revised: 8/3/89  
Security: Everyone

Network Termination Issues: "The Terminator" (Part 1 of 2)

=====

Termination is the process of "ending" an electronic signal on a network after it has been broadcast to all the devices on that network. Without termination, signals bounce back and can interfere with new signals. On short networks, or networks with little traffic, these reflections usually present no problem. But as networks grow, correct termination becomes a critical factor. If your customers' networks are expanding, or your business is large network installations, then your understanding of network termination could mean the difference between reliable networks your customers can trust, or technical support headaches for them and you both.

### When Termination Becomes an Issue

-----

There are several predictable occasions when termination becomes an issue in AppleTalk network management.

A network manager's first encounter with termination issues often occurs when switching from Apple's LocalTalk cabling to the PhoneNET System. Farallon's PhoneNET System is based on telephone wiring as opposed to shielded cable. The advantage in switching to PhoneNET Connectors and existing telephone wiring is both economy and flexibility. Because PhoneNET Connectors are not self-terminated, the network manager can set up the network in a variety of ways, and run cable over longer distances. But he will need to manually terminate the network using the terminating resistors supplied with PhoneNET Connectors.

Second, the Macintosh network administrator very frequently receives requests to add more devices, and thereby add to the network's length. Whereas networks constructed with LocalTalk shielded cable are limited to 1,000 feet, a network running over the standard, 24 gauge phone cable found in most homes and offices can extend up to 3,000 feet. Short runs may work well without termination, but with additional network length and devices, termination becomes more important. Proper termination of network segments will cleanly absorb signals, and allow greater distances without the risk of signal reflection.

Third, just as in a freeway system for automobiles, light traffic usually moves well no matter what the technical shortcomings of a given stretch of road. But with added traffic, any minor engineering flaw will cause traffic jams. The same is true in AppleTalk networks. Most early Macintosh networks were created for light traffic: to share printers, or to transfer small files around a workgroup. Over the last two years the number and complexity of workgroup services that depend on workstation connectivity has increased dramatically. Large AppleShare file servers, PC-Novell network services, DEC/VMS connectivity, heavy traffic generated by electronic mail, as well as newer network applications like Farallon's Timbuktu screen-sharing software, have placed significant burdens on the network.

More traffic on longer networks makes more of these services susceptible to disruption by reflected signals. One common symptom of heavy traffic and poorly terminated wiring is that devices disappear intermittently in the Mac Chooser. This phenomenon is known as "ghosting" or "drop-out."

Proper Termination, "Self-Termination," and LEDs

-----

All LocalTalk network connectors use mini-transformers to couple devices to the network and provide electrical isolation from noise and potentially harmful surges. All currently available network connectors--LocalTalk, PhoneNET, TurboNET, and so on -- offer these features. However, each one of these connectors is also very different:

- The Apple LocalTalk Connector Box. Apple added a unique feature to their LocalTalk connector box, a terminating resistor, which is mechanically disengaged when the shielded cable connecting one connector to another is inserted in an open port. All connectors in a daisy chain have cable plugged into both ports, except, of course, the connectors at each end of the chain, precisely where termination is necessary. Thus the simple genius of Apple's approach. LocalTalk connector boxes, which are limited to shielded cable, daisy chain topologies, and distances no longer than 1,000 feet, are the ONLY true self-terminating connectors for AppleTalk networks.

- The PhoneNET Connector. The PhoneNET Connector is unterminated by design, allowing the network manager to properly terminate the network by installing the recommended 120 ohm terminating resistors where needed. It is important to emphasize that only 120 ohm terminating resistors provide the correct value of termination. Placed at the ends of network segments, the 120 ohm terminating resistors packaged with PhoneNET Connectors will effectively prevent signal reflections, while allowing for a variety of network topologies.

PhoneNET Connectors disperse voltage spikes by use of "MOVs" (metal oxide varistors). MOVs are circuits that respond much faster to transient voltage spikes than neon bulbs, which disperse spikes as light. This means that during a surge, PhoneNET Connectors disperse spikes as heat and allow much less energy to bypass the protection circuit and enter the isolation transformer.

- LED-Based Connectors. Neon bulbs, such as those found in the Nuvotech ST Connector and others, glow when they encounter network spikes. However, the technology of neon bulbs is both slower than MOVs and also doesn't offer any quantitative information about network voltage status.

LEDs form part of the "self-termination" circuit. The value of termination is not constant, however, but varies depending on signal strength. Unfortunately, in no case is the termination of the correct value, and therefore reflections can occur, causing the predictable problems in longer network segments, or when traffic is heavy.

Finally, LEDs tell the network manager very little about how the network is working. LEDs measure all electrical signals passing through the connector, without differentiating between new signals and bad packets reflected back onto the network. For detailed assessment of network activity, inexpensive management software like Farallon's CheckNet or TrafficWatch are far better tools than blinking LEDs. These management tools offer reliable, quantifiable information which can be charted and tracked over time.

Now Stay Tuned

-----  
Self-terminating connectors are attractive in that they make manual termination of the network unnecessary. But the fact is that manually terminating the network allows network managers to construct networks that perform reliably even while expanding and changing in unexpected ways. With terminating resistors in the connectors, the network manager faces the risk that someone will interfere with the correct termination of the network simply by removing his machine (and its attached connector). The network could malfunction because someone took his Mac home for the night, or away on a trip. LocalTalk networks typically undergo lots of spot changes, steadily increasing usage, and unplanned expansions (like an extra device temporarily added to the network). PhoneNET Connectors were designed with these changes in mind.

Besides very short, lightly trafficked networks, there is one other case when the convenience of self-terminating connectors poses no threat to the proper functioning of the network. If your customer's network is built around one or more PhoneNET StarControllers, with one user (branch) per port, reflections on any one branch effect only the user on that port. Overall network performance won't suffer if that user mistakenly removes his connector, because each StarController port supports a separate physical network. The one user/port active star network offers significant advantages for the network manager, who gains greater control over the growth of the network, and thereby its reliability. Stay tuned for more news from Farallon on connectors for active star topologies.

Article Change History:

## AppleTalk Internet Router: Setup Considerations

Revised: 9/22/89  
Security: Everyone

AppleTalk Internet Router: Setup Considerations

=====

This article last reviewed: 20 July 1989

These are some items to keep in mind when setting up the AppleTalk Internet Router:

### Memory Considerations

-----

- In general 1MB of RAM is sufficient for running the router. However, you should consider the following exceptions:
- You must use 2MB of RAM when running the router concurrently with the AppleShare File Server. You can add memory beyond 2MB, but that only increases performance of the file server and not of the router. The reason is that the file server uses all additional memory for its RAM cache.
- It is recommended that you use 2MB of RAM to run the router and the AppleShare Print Server or the router and a mail server package concurrently. As long as you have 2MB of RAM, you can also run the router, the AppleShare File Server, and any single foreground application, like a print server.
- To avoid memory problems, do not use MacroMaker on a 1MB router machine.
- Be aware that having MacsBug (or any other debugger) active reduces the amount of memory available to the router. Do not run MacsBug on a 1MB router machine or on a router that is also running the AppleShare File Server.
- To avoid memory problems, do not use 32-bit QuickDraw on a 1MB router machine.
- Best use of memory can be obtained by minimizing the INITs and desk accessories that run concurrently with the router.
- Because of the way MultiFinder runs desk accessories, we recommend that

you run the router in single Finder. MultiFinder runs desk accessories in the system heap. This means that when you use the router desk accessory under MultiFinder, you are more likely to run out of memory, because the router driver and any other concurrently running process take memory from the system heap.

## Printing

-----

Note that the following considerations refer to printing from the router machine. These considerations do not refer to a workstation printing, even if it reaches a printer through a router.

- Avoid background printing on a router machine. When Print Monitor opens a printer driver, it uses up memory; the router desk accessory may then run out of memory.
- Do not attempt 32-bit color printing from a router machine.
- Be aware that the 6.0 LaserWriter driver takes up much more memory than the 5.2 driver. Avoid using the 6.0 LaserWriter driver on a 1MB router machine. Also avoid using the 6.0 LaserWriter driver, when running the router and the AppleShare File Server concurrently.

## INITs and Desk Accessories

-----

- INITs and desk accessories are not always well-written. They sometimes use up memory behind the operating system's back. Try to live with as few of them as possible.
- Close unneeded desk accessories. This includes the Chooser, which would otherwise continually broadcast look-up requests on the network.
- Responder is OK when installed with the Router.

## Upgrade Utility

-----

- If a Phase 1 router is introduced to the internet after the routers have been running in Phase 2 mode with network ranges for at least 15 minutes, the Phase 2 routers issue an alert and do no conversion. You must restart the router Macintoshes with the Upgrade Utility installed to restart the conversion.

## System Software

-----

- The Router has been tested with System 6.0.3 and will be tested with future releases. Older systems are not recommended.

## Hard Disks

-----

- The Router is RAM based. A faster hard disk will not cause faster routing of packets. (Improvements can be seen when using a faster hard disk with the AppleShare File Server).

#### EtherTalk Card

-----

- You should use a revision J or later EtherTalk card with the router.

- An improperly terminated EtherTalk card or a break in the EtherTalk cable causes the router to take a very long time to load. An EtherTalk card not connected to a cable must have a BNC "T" connector attached and terminators attached to the "T".

- Make sure your EtherTalk card is properly set for thick or thin Ethernet. If it is improperly set, no workstations or other routers on the network can communicate with the router.

#### Removal of AppleShare File Server

-----

- The removal of AppleShare File Server software after installation of the Router/EtherTalk/TokenTalk software will remove the AppleTalk file from the System Folder. You must re-install either the router, EtherTalk 2.0, or TokenTalk 2.0 software.

#### Installation

-----

- When using the router with TokenTalk, be aware that some customers were seeded with an AppleTalk Phase 1 (1.0) version of TokenTalk. You should remove TokenTalk 1.0, using the 1.0 Installer diskette, and then install TokenTalk 2.0.

- Be aware that some customers were seeded with an AppleTalk Phase 1 (1.0) version of the AppleTalk Internet Router. You should remove the 1.0 version, using the 1.0 installer diskette, and then install the 2.0 version. The ADEV files for the LocalTalk ports were renamed with the 2.0 version of the AppleTalk Internet Router. If you do not remove the 1.0 version of the router, the router setup window will show the old and new ADEVs, causing you to have 4 LocalTalk ports.

## ImageWriter II: Color Ribbon Problem Solved

Revised: 8/3/89  
Security: Everyone

ImageWriter II: Color Ribbon Problem Solved

=====

This article last reviewed: 6 June 1989

Here's the problem:

When turning on the ImageWriter II, the carriage assembly moves to the left and then back to center. At this point, the color ribbon assembly rotates counter-clockwise, causing the ribbon frame assembly to drop. As the color ribbon assembly rotates counter-clockwise, it hits a small copper tab called the ribbon shift spring tab.

When this tab is hit, it causes the color ribbon assembly to reverse rotation and lift the ribbon frame assembly back up to its normal position. Using the carrier shaft as a reference axis, the tab is about 45 degrees from the axis.

If the tab gets pushed away from the carrier shaft more than 45 degrees, it is not in its proper position to reverse the rotation on the color ribbon assembly. Thus, the ribbon frame assembly remains down and will not come up to its proper position.

To cure this, push tab back towards the carrier shaft, until it causes the normal change of rotation and let the ribbon frame assembly come back up to its normal position.

## LaserWriter II: Specs for Paper and Transparencies

Revised: 2/12/93  
Security: Everyone

LaserWriter II: Specs for Paper and Transparencies

=====

Article Created: 3 August 1989

Article Change History

-----

02/12//93 - UPDATED

- Vendor information:

This article contains information about papers, envelopes, labels, and transparencies for use with the LaserWriter II.

The "LaserWriter II Owner's Guide" specifies the paper at:

"16-lb. to 20-lb. photocopy or typewriter bond (60 to 80 g/m2) in normal mode; up to 36-lb. (135 g/m2) stock in manual mode with face-up tray open. Accepts most letterhead and colored stock. Accepts medium-weight photocopy transparencies. Envelopes can be printed with manual feed or from the envelope cassette. Labels can be printed using manual feed."

Beyond this information, Apple has no documented specifications for paper requirements. However, the following information is also available in the Tech Info Library on AppleLink:

When choosing an acetate transparency for use in a LaserWriter II, it is important to consider the temperature of the printer's fuser roller, and the amount of time the acetate sheet is in contact with the roller.

The temperature of the LaserWriter II fuser roller varies from:

329 to 356 degrees Fahrenheit (165 to 180 degrees Centigrade)

An 8.5 by 11-inch sheet of paper or acetate takes approximately 5.8 seconds to travel over the fuser roller. This works out to be about 1.5 inches per second.

The LaserWriter II accepts medium weight photocopier transparencies like

Scotch #503, catalog # 15921-3.

For sources, check the following:

James River Corporation, Pro-Tech Paper Division, specializing in papers, film, and adhesive labels for the LaserWriter

Products:

Pro-Tech Laser labels (white and clear)

Pro-Tech Laser envelopes (white)

Pro-Tech Laser bond paper (white and assorted colors)

Pro-Tech Laser transparency film

Avery, Avery and Dennison Divisions, paper products, specializing in transparencies and labels for the LaserWriter.

Products: Laser adhesive labels - 5260, 5261, 5262

Laser Transparencies - 5182 and 5282

To locate a vendor's address and phone numbers, use the vendor name as a search string.

## AppleFax Software Version 1.2: Improvements and Functionality

Revised: 9/2/93  
Security: Everyone

AppleFax Software Version 1.2: Improvements and Functionality

=====

Article Created: 3 August 1989  
Article Reviewed/Updated: 2 September 1993

TOPIC -----

Apple no longer provides AppleFax software, and it isn't compatible with System 7. If you're looking for fax software to use with System 7 and the AppleFax Modem, contact Delrina Technologies for software called "Fax Pro for Macintosh."

To locate a vendor's address and phone numbers, use the vendor name as a search string.

This article presents information about AppleFax 1.2 that was required for system software version 6.0.3.

DISCUSSION -----

Here's a list of improvements made to AppleFax version 1.2:

- Version 1.2 of AppleFax firmware fixes incompatibility with some Group 3 facsimile machines and certain PBX phone systems.
- Software version 1.2 eliminates overlapping characters, which sometimes occurred with version 1.1. Also, the new version correctly transmits envelopes containing documents of differing page sizes.
- Version 1.2 greatly improves the performance of the "In care of" feature.
- AppleFax software version 1.2 is required for use with System 6.0.3 and is, therefore, required for operation on the Macintosh SE/30. Version 1.1 doesn't work with System 6.0.3 or future versions of system software.

## Compatibility Testing

-----

The AppleFax Modem conforms to the published CCITT Group 3 facsimile standard. All facsimile devices should conform to this standard to ensure complete compatibility with other facsimile devices. Apple has tested AppleFax with over 40 Group 3 facsimile machines from the major manufacturers. While no significant problems remained during testing, Apple doesn't guarantee that AppleFax always works with every Fax machine due to phone line and equipment variations.

## AppleFax Functionality

-----

The product must interact with the Macintosh system, applications software, and the public phone system, each of which can affect its performance and reliability. Some things to keep in mind regarding the AppleFax:

- AppleFax isn't intended to replace freestanding facsimile machines. If your work demands numerous Fax messages continually received, or if you must send a large number of handwritten documents, a Fax machine will work best. However, for Macintosh owners, AppleFax can be a terrific complement to their Fax machine.
- The AppleFax product is at its best when used as a Fax creation and transmission station. The image quality of an AppleFax document is much better than most other forms of Fax transmission.
- AppleFax provides convenience in automatically sending a document to multiple destinations or automatically sending documents while unattended (for example, at night, when phone rates are least expensive). Most Fax machines are incapable of unattended document transmission.
- Macintosh data and program files can be transmitted between AppleFax stations even faster than using 2400-baud data modems.
- Just as with bit-mapped printing devices (the Apple ImageWriter II, for example), the performance of AppleFax improves when running on a faster Macintosh.
- AppleFax is tested and approved for sale and use only in the U.S. and Canada. The product is not designed for use with, nor approved by, any other countries' public telephone and telegraph agencies.

AppleFax software provides basic facsimile functionality for the majority of AppleFax users. It doesn't provide background operation (the ability to send and receive files while using another Macintosh application) or the Cut/Copy/Paste functions on received Fax images. If you require these features, look into a third-party software package.

## Apple II Workstation Card: No Apple IIGS Support (2/97)

Revised: 2/12/97  
Security: Everyone

Apple II Workstation Card: No Apple IIGS Support (2/97)

=====

Apple II Workstation Card: Apple IIGS Support (2/97)

Article Created: 03 August 1989  
Article Reviewed/Updated: 12 February 1997

TOPIC -----

This article discusses the Apple II Workstation card and Apple IIGS support.

DISCUSSION -----

The Apple II Workstation Cards is not supported in the Apple IIGS because of the following reasons.

\* When the Apple II Workstation Card is installed, only ProDOS 8 applications can run. The Workstation Card tells the server that it is an Apple IIe. Therefore, it will not work in a ProDOS 16 network environment. Typically, this means only the first 64K of memory will be used.

\* The Workstation Card is not fully tested in this configuration and it is not supported by Apple.

## LaserWriter: How to Use with Colored Paper

Revised: 12/6/89  
Security: Everyone

LaserWriter: How to Use with Colored Paper

=====

This article last reviewed: 6 June 1989

Some people have that some colored papers fade when used in a LaserWriter. Before committing to any type of paper, consider the manual's advice. Page 129 of the LaserWriter IINTX manual carries the following specifications for printing paper-based materials:

"16-lb. to 20-lb. photocopy or typewriter bond (60 to 80 g/m<sup>2</sup>) in normal mode; up to 36-lb. (135 g/m<sup>2</sup>) stock in manual mode with face-up tray open. Accepts most letterhead and colored stock."

Any paper that meets the above specifications and is designed for photocopier use should work properly and show no discoloration. The best method for determining if colored paper will discolor is to test it.

Note: The fuser generates temperatures between 165 and 180 degrees centigrade.

## MacWorkStation: Protocol-Based Communications Problem

Revised: 8/3/89  
Security: Everyone

MacWorkStation: Protocol-Based Communications Problem

=====

This article last reviewed: 12 April 1989

A developer of a TCP/IP network reports the following problem. Uploads of window or file contents are causing serious problems resulting in line drops. This occurs during EZ read Text (T008), Read Text (T009), Select Existing File (F017), and probably during EZ Read File Fork (F007) and Read File Fork (F008).

The developer is currently using the Simple ASCII transport layer (ID = 2) with 7 data bits. Unfortunately, data in the ranges <00>-<1F> and <80>-<FF> may be contained within windows or files. In particular, if there is a carriage return <0D> within the data, then the IBM mainframe front-end processor (FEP) takes this as an end-of-line character, sends the packet to CP, which sends the packet to the application, which processes it.

Meanwhile, MacWorkStation continues to send the remainder of the packet up until the final carriage return, which it uses to signal end-of-line. Unfortunately, the characters following the first carriage return cause CP interrupts, leaving the virtual machine in CP mode. After some number of interrupts, CP determines that the line is too noisy to continue and signals the FEP to drop it.

The problem here is that they are using a protocol in an unsupported fashion. The serial protocol driver (ID=2) that uses start and stop characters is not designed to support the transfer of binary data, or any data that might contain nonstandard characters. The best choice would be to use the serial driver (ID=1) that supports binary data and should be able to handle the transfer of carriage returns. If this is unacceptable, request a copy of the source for serial driver version 2.

## GS/OS: Corrupt File Changes Icons

Revised: 9/22/89  
Security: Everyone

GS/OS: Corrupt File Changes Icons

=====

This article last reviewed: 14 April 1989

A number of reports have appeared, concerning changing icons under GS/OS. For example, in the case of MultiScribe GS, instead of the pens and paper icon, the user sees the generic, diamond-shaped, system-defined application icon. The problem may be quite simple: one or more corrupted icon files.

GS/OS (System Disk version 4.0) stores Finder icons in a file called FINDER.ICONs. Application/document icons are stored in files that typically end with .ICONs.

The Finder can match files to icons by any combination of three file identification fields. The icon can match by file type, AUX type, and filename. The Finder keeps a list of icon files. The first list the Finder reads is FINDER.ICONs from the start-up disk's ICON folder. Next, the Finder adds any other icon files it finds in the ICONs directory of inserted disks. Additional files are added to the front of the list so that FINDER.ICONs is always the last in the list.

When the Finder needs to match a file to an icon, it starts with the first icon in the list. A match can be made by an exact match or by use of a wild card. If all three fields in the icon match the file, the file is given that icon. If even one field does not match, the Finder tries again with the next icon in the list. The Finder continues to try to match icons with files until it reaches the last icon in the FINDER.ICONs file. This is the generic document icon. It will always match all three fields.

The loss of icons is probably due to a missing or corrupted .ICONs file. For MultiScribe, locate the .ICONs on the original MultiScribe disk. Copy the MultiScribe .ICONs file to the ICONs folder on the hard disk. On restart, the application should take on its proper icon. Once the icons are reattached to the application and the document, you should be able to double-click the document.

Locating and transferring the .ICON file for other applications, documents,

and NDAs should also reattach the missing icons.

The icon representing the application ProDOS should appear as the generic application (paper and hand) icon. The icon of a 3.5-inch disk is assigned to represent disks inserted in 3.5-inch drives. Apple-distributed New Desk Accessories (NDAs) have the generic document (paper with folded corner) icon.

GS/OS 4.0: Control Panel Date Problem

=====

This article last reviewed: 18 April 1989

This problem describes a problem with GS/OS 4.0.

When the Control Panel date is set to the 31st of any month, GS/OS 4.0 sets the date created/modified on files to "<No date>" or "\$0000". There is currently no workaround.

## AppleSoft BASIC: Network Problems And Solutions

Revised: 8/3/89  
Security: Everyone

AppleSoft BASIC: Network Problems And Solutions

=====

This article last reviewed: 23 April 1989

This article discusses four problem areas concerning AppleSoft BASIC and networks:

- Problems due to an incorrect file name.
- Problems caused by interrupts
- Problems with printer timeouts
- Problems with "LIST" and similar commands.

### Incorrect File Names

-----

Occasionally, there are reports of difficulties printing or saving files using "BASIC.System" from within Aristotle. Problems can appear because of an incorrect file name. Note that the distribution disks do not contain a file with the name "BASIC.System". Rather, they show a file with the name "BASIC.SYSTEM". If "BASIC.System" is being called, and only "BASIC.SYSTEM" is available, a message stating that the file cannot be found is the response. If both the Aristotle designation and the filename are the same, there is no conflict.

### Interrupt Problems

-----

The only known problem when using Applesoft BASIC over the network concerns turning off interrupts from BASIC. If the BASIC program turns off the computer's interrupts, network difficulties occur. Interrupts are used by the network to prioritize communication with workstations. Should these interrupts be disabled, the network could "hang", because communication with the workstation is not possible.

### Printer Timeout

-----

If you issue the "PR#7" command, printed within 30 seconds, and issued "PR#0", then everything works fine. However, if you type "PR#7" and do not close after printing with a "PR#0", there's a problem. After about 2 minutes, when you try to print again, nothing happens. The printer times out. You must close the printer connection for everything to function correctly.

#### "LIST" And Other Printer Commands

-----

Another printer issue has to do with the "LIST" command. For example, if, while trying to print a BASIC listing, you type "PR#7" and immediately type "LIST", you won't get a printout of the listing. The reason for this failure relates to how quickly you type "LIST". After you type "PR#7", it takes 3 to 5 seconds for the workstation and the networked printer to establish communication. If you type "LIST" before this communication link is completed, the command will not be recognized as input. As a result, the printout shows only two Applesoft prompts (the right bracket, "]").

To be assured that the computer accepts the "LIST" command (or any immediate command that causes printing), wait until the cursor returns to the screen after typing "PR#7", before entering the next command. This way, you know the network has "digested" the command. After finishing the print job, remember to close the printing session by typing "PR#0".

## AppleWorks to LocalTalk ImageWriter: Printing Problems

Revised: 8/3/89  
Security: Everyone

AppleWorks to LocalTalk ImageWriter: Printing Problems

=====

This article last reviewed: 6 June 1989

Some users have complained of an inability to print either from an Apple IIe or from an Apple IIGS across an LocalTalk network to an ImageWriter II when using AppleWorks. All reported being able to print from BASIC using PR#7. Although the networks could have rather different configurations and software, these facts were the same.

The difficulty in printing concerns the version of AppleWorks being run from the server. The ability to print from Applesoft indicates that the hardware is properly configured. AppleWorks 2.0 is not licensed for, nor designed for, running from an AppleShare server. For a version of AppleWorks licensed and designed for running from a server, use AppleWorks version 2.1N. Be sure, in AppleShare Admin under the Apple II menu, to set the user's account to the desired printer. The alternative would be to run AppleWorks 2.0 from a local disk.

The printing procedure is the same whether you start across the network or you startup locally. However, the network version of AppleWorks is required, if it is to be run from the server. Here is some background information, relative to this inquiry.

- Aristotle has no effect on the ability to print from AppleWorks.
- The location of ATINIT differs when on a server (as compared to a local disk). On the server, ATINIT should be in the folder assigned to the user. For example: ProDOS.SERVER/USERS/(\_user's name\_)/SETUP/ATINIT.
- The name of the System.APPS subdirectory is not critical, as long as a consistent name is used throughout the network.
- The WWSS file is not necessary for the operation of AppleWorks.

## Televideo Terminal Emulators for the Macintosh

Revised: 8/3/89  
Security: Everyone

Televideo Terminal Emulators for the Macintosh

=====

This article last reviewed: 23 May 1989

As of May 1989, the only Televideo terminal emulation packages for the Macintosh are for the Televideo 950 and the Televideo 925. The Televideo 924 was not in evidence. Palantir's "InTalk" package for 925 emulation did not work.

However, if you need to log onto a Honeywell host that requires the Televideo 924, you can use the Telescope programmable terminal emulation package, you can program in the escape sequences for the 924. The emulation works fine except for one thing: Telescope has no facilities for video attributes, such as half-bright, colors, blinking, underlines, and so on.

Telescope uses the standard Macintosh two-bit video display. This setup makes programming intensity and color impossible. Supposedly, the package supports underlines, but not flashing characters. Intensity and color are available on the Macintosh II display, but new software will have to be written specifically for the system.

## MacTCP: Recommended DDP-IP Gateways (1/95)

Revised: 1/27/95  
Security: Everyone

MacTCP: Recommended DDP-IP Gateways (1/95)

=====

Article Created: 16 May 1989  
Article Reviewed/Updated: 27 January 1995

TOPIC -----

This article is about DDP-IP (Datagram Delivery Protocol/Internet Protocol) gateways. It presents an overview of TCP/IP and MacTCP and discusses DDP-IP gateways recommended for use with MacTCP.

DISCUSSION -----

MacTCP

-----

TCP/IP networks are widespread, especially in university, scientific, and engineering environments. UNIX systems have distributed TCP/IP as a standard.

MacTCP provides TCP/IP protocols to the Macintosh OS. It offers TCP/IP services (UDP, TCP, Domain name mapping) to applications. For example, a Telnet application for remote terminal service over a TCP/IP network would call MacTCP.

MacTCP is software only and runs over Ethernet. MacTCP also runs over LocalTalk, in which case a DDP-IP gateway is required.

DDP-IP Gateways

-----

If you have an AppleTalk network and want to communicate with a TCP/IP network, you require a "DDP-IP" gateway. This gateway encapsulates TCP/IP packets into AppleTalk (DDP) packets for sending over the AppleTalk zone to the target Macintosh. In turn, the gateway receives encapsulated packets from the Macintosh and strips out the TCP/IP packet for forwarding to the TCP/IP target.

MacTCP supports the encapsulation process, so that a Macintosh on LocalTalk can access TCP/IP networks and services on a TCP/IP Ethernet. Three commercial sources for gateways are Apple Computer, Shiva, and Cayman. There is also Stanford University's KIP software, a noncommercial alternative. To locate a

vendor's address and phone number, use the vendor name as a search string.

The Apple IP Gateway is Macintosh software which allows Macintosh computers using AppleTalk (Apple Remote Access, LocalTalk, or EtherTalk) to access IP services on an IP internet. MacTCP is required on both the client Macintosh and the gateway Macintosh.

The Shiva FastPath 5 is the latest version of their LocalTalk-EtherTalk bridge. KSTAR is the configuration and management software for the box; KSTAR offers DDP-IP gateway services.

The Cayman GatorBox is a LocalTalk-EtherTalk bridge, an NFS-AFP gateway, and a DDP-IP gateway.

Stanford University's KIP software provides DDP-IP gateway services among other things. It runs on the FastPath 2 from Shiva. It is NOT a commercial product and, therefore, is not supported. It currently requires UNIX daemons to configure the software. The only people who should try KIP are capable network engineers with UNIX knowledge, who require no support.

Apple recommends that users choose commercially-supported software to ensure that their needs are met. The vast majority of users requiring a DDP-IP gateway should consider the Apple IP Gateway, Cayman GatorBox, or Shiva FastPath 4 (not 2 or 3) with KSTAR software.

## MacPeak SCSI Drive: How to Use with an Apple IIGS

Revised: 8/3/89  
Security: Everyone

MacPeak SCSI Drive: How to Use with an Apple IIGS

=====

This article last reviewed: 23 May 1989

Some people have had problems formatting a MacPeak external SCSI drive (normally for the Macintosh) from an Apple IIGS. One user, who had this problem, was working with an Apple IIGS with 1MB RAM, 3.5-inch and 5.25-inch floppy disk drives, and an Apple II SCSI card in slot 5.

The Apple IIGS recognizes the drive, but the format routine quits after running for about the same time it takes to format a ProDOS floppy and then crashes. A conflict between the SCSI card and the 3.5-inch drive causes this problem.

The 3.5-inch drive plugs into the SmartPort. The SmartPort is slot 5. To use the SCSI card in slot 5, you need to set slot 5 in the Control Panel to "Your Card". When the Control Panel is set in this way, the SmartPort is disabled, and the 3.5-inch drive is also disabled.

To use both the 3.5-inch drive and the SCSI drive on the Apple IIGS, place the SCSI card in a slot other than slot 3 (the 80-column display), slot 4 (the mouse connection), slot 5 (the SmartPort), or slot 6 (the 5.25-inch drive location). This leaves slots 1, 2, and 7 available. Slot 1 is often used for a printer, slot 2 is often used for a modem, and slot 7 is used for AppleTalk. Choose slot 1 if no printer is attached, slot 2 if no modem is attached, or slot 7 if AppleTalk is not in use. No matter which slot you choose, you must set the Control Panel to "Your Card" for that slot.

If, after reassigning slots, there is still difficulty formatting the MacPeak drive, there would appear to be an incompatibility between the SCSI card and the MacPeak drive. (MacPeak indicated that they do not support the use of their drives on the Apple II SCSI card.)

## LaserWriter Family: Paper Specifications

Revised: 12/6/89  
Security: Everyone

LaserWriter Family: Paper Specifications

=====

This article last reviewed: 23 May 1989

Any number of things can have an impact on how well a LaserWriter prints, including moisture content (the room must have a 70% to 90% moisture level, the paper must be moisture-wrapped, and the paper must be fresh) and smoothness. A too smooth paper (for example, measuring only 50 sheffields) can cause smudging as easily as paper that is too dry.

For reference, Apple recommends the following paper specifications for use with its LaserWriters:

|                   |                                                    |
|-------------------|----------------------------------------------------|
| Basic Weight:     | 60 to 135 grams-per-square-meter (16- to 35-pound) |
| Caliper:          | 3.7 to 7.5 mils                                    |
| Moisture Content: | 4% to 6% by weight                                 |
| Smoothness:       | 100- to 300-sheffield                              |
| Grain:            | long grain                                         |

## HyperCard: Auto Hilite Problem

Revised: 7/17/92  
Security: Everyone

HyperCard: Auto Hilite Problem

=====

Article Created: 23 May 1989  
Article Last Reviewed: 4 June 1992  
Article Last Updated:

A user has reported a problem in HyperTalk, up to and including version 1.2.2.

A button script cannot manipulate text that is selected in a field, if the button is set to Auto Hilite. When Auto Hilite is on, the text is deselected to flash the Auto Hilite attribute. Subsequently, the text is not reselected. Thus, the script has nothing to select.

For example, a user selects some text in card field. The button script takes the selection and displays it in another field.

```
on mouseUp
    put selection into it
    put it into card field show_me
end mouseUp
```

If you assign the button the Auto Hilite attribute, this technique will not work, because the button is highlighted before the text can be deselected and passed to the variable.

The following script uses a global variable and three handlers. It requires the Auto Hilite attribute of the button to be turned on. Because a "mouseWithin" message is generated before the button is highlighted, you can save the selected text before it is deselected. As a bonus, you can also save the selection and restore it when done.

```
on mouseWithin
    global temp
    put selection into item 1 of temp
    put the selectedChunk into item 2 of temp
end mouseWithin
```

```
on mouseUp
  global temp
  put item 1 of temp into card field show_me
  select item 2 of temp
end mouseUp
```

```
on mouseLeave
  global temp
  select item 2 of temp
end mouseLeave
```

This script provides the same result as the previous script. It uses no global variables and requires only one handler. As with the previous script, you must have the button's Auto Hilite attribute turned off. If you are running out of global variables, this routine is better than the previous script, because it has no global variables. However, the script is much slower.

```
on mouseDown
  put the selection into temp1
  put the selectedChunk into temp2
  set hilite of me to true
  repeat while the mouse is down
    if PointInRect(the mouseLoc, the Rect of me) = true then
      set the hilite of me to true
      select temp2
    else
      set the hilite of me to false
      select temp2
    end if
  end repeat
  if PointInRect(the mouseLoc, the Rect of me) = true then
    put temp1 into card field show_me
  end if
  set the hilite of me to false
  select temp2
end mouseDown
```

```
Function PointInRect thePoint, theRect
  if (item 1 of thePoint > item 1 of theRect) and *
    (item 1 of thePoint < item 3 of theRect) and *
    (item 2 of thePoint > item 2 of theRect) and *
    (item 2 of thePoint < item 4 of theRect) then
    return true
  else
    return false
  end if
end PointInRect
```

\*You must insert a "soft" return (Option-Return) at these locations. (Do not type these asterisks as part of the script.)

## LaserWriter IINTX: Printing in HP Emulation Mode (1 of 3) (2/95)

Revised: 2/23/95  
Security: Everyone

LaserWriter IINTX: Printing in HP Emulation Mode (1 of 3) (2/95)

=====

Article Created: 23 May 1989  
Article Reviewed/Updated: 23 February 1995

TOPIC -----

This article describes how to make a LaserWriter IINTX print the Pound Sterling character in Hewlett-Packard LaserJet Plus emulation mode. In doing so, it describes the difference between PostScript codes and ASCII character codes. It also gives step-by-step instructions for how to print from a LaserWriter IINTX in HP LaserJet Plus Emulation mode from an MS-DOS computer either via a serial connection or via AppleTalk. Part 2 covers troubleshooting, while part 3 is a table of the upper 128 ASCII characters for HP LaserJet Plus emulation.

DISCUSSION -----

The LaserJet Plus emulation mode uses the ROMAN-8 symbol set used by the HP LaserJet. This is different from the standard LaserWriter character set. The LaserWriter PostScript characters are not really ASCII values, because they are mapped, character definitions and belong to a character set.

These values can be remapped, at will, to an output character. The standard LaserWriter set defines the Pound Sterling as character code 243. The ASCII value for the character is 187. Once again, the character code is not an ASCII value; it is a mapping reference used by PostScript. PostScript character codes are not available in the LaserWriter HP LaserJet emulation mode.

To print the sterling character, the following steps and information must be taken into account.

There is a problem trying to print characters, like the Pound Sterling, in HP LaserJet emulation on the LaserWriter IINTX. If you are using a serial connection, the following instructions must be used.

The problem appears when printing the upper 127 ASCII characters and graphics (ASCII values 128 through 255). This is due to the serial port DIP setting of 7 data bits. To attain full emulation, configure the serial port as described in

the steps below.

NOTE:

Currently, there is no available method of software switching back to PostScript or any other emulation mode once you leave the PostScript mode. The correct method is to change the DIP switch settings and wait 30 seconds. If you want PostScript, set switch 1 to the DOWN position. Wait 30 seconds and place the switch back to the UP position.

Printing in HP LaserJet Plus Emulation Mode from an MS-DOS Computer  
=====

Step 1 - Connection  
-----

Connect a 25-Pin Serial Cable to the 25-pin serial port on the LaserWriter IINTX. Connect the other end to a serial port on the PC.

NOTE:

Most serial ports for PCs use a male DB-25 connector and the LaserWriter IINTX uses a female DB-25 connector. You need to use a straight pin-to-pin female-to-male DB-25 cable.

Step 2 - Switch Settings  
-----

While the LaserWriter IINTX is off, set the printer DIP switch settings to:

- 1 UP
- 2 DOWN
- 3 UP
- 4 UP
- 5 UP
- 6 DOWN

These switch settings place the LaserWriter IINTX in:

PostScript Batch Mode,  
RS-232 9600 baud,  
RS-422 9600 baud,  
7 data bits, no parity check, 1 stop bit, with DTR/DSR handshake.

Step 3 - Power On  
-----

Turn on the LaserWriter IINTX and the PC. After a few seconds, the LaserWriter II will print a test page containing its current settings (listed above).

Step 4 - PostScript Code  
-----

The PostScript code that follows switches the LaserWriter II into LaserJet+ emulation mode.

Caution:

-----  
If you choose to use the PostScript code provided in this article, you assume all risks involved in making these changes. PostScript code, if not entered correctly, can place the LaserWriter into a condition requiring service.

NOTE:

The "%" characters and following comments are not necessary. Remove them when typing the program.)

- For DTR/DSR, from the DOS prompt, type:

```
COPY CON POST.TXT
%=====
% Begin PostScript Code
%
serverdict begin 0 exitserver %Exits the printer server loop.
statusdict begin           %Starts modifying settings.
9 0 3 setsccbatch           %Turns off the RS-422 9600-baud port.
25 9600 68 setsccbatch      %Sets the 25-pin RS-232 9600-baud port to 8 data
%                             bits.
5 setsoftwareiomode         %Sets printer to HP LaserJet+ mode.
0 sethardwareiomode         %Sets communications mode to serial.
end                         %This is the end of the mode switch routine.
systemdict/quit get exec    %Forces an error to cause a system start test
%                             page.
(Control-Z)                 %The keyboard Control key and the Z key together.
%                             This ends text editing and saves the file.
%
% end PostScript Code
%=====
```

- For XON/XOFF, from the DOS prompt, type:

```
COPY CON POST.TXT
%=====
% Begin PostScript Code
%
serverdict begin 0 exitserver %Exits the printer server loop.
statusdict begin           %Starts modifying settings.
9 0 3 setsccbatch           %Turns off the RS-422 9600-baud port.
25 9600 64 setsccbatch      %Sets the 25-pin RS-232 9600-baud port to 8 data
%                             bits.
5 setsoftwareiomode         %Sets printer to HP LaserJet+ mode.
0 sethardwareiomode         %Sets communications mode to serial.
end                         %This is the end of the mode switch routine.
systemdict/quit get exec    %Forces an error to cause a system start test
%                             page.
(Control-Z)                 %The keyboard Control key and the Z key together.
%                             This ends text editing and saves the file.
%
% end PostScript Code
```

%=====

#### Step 5 - Batch File

-----

A batch file must be created to set up the PC communications port and to send the PostScript code to the printer.

From the DOS prompt, type:

```
COPY CON HPMODE.BAT
MODE COM1:96,N,8,1,P
MODE LPT1:=COM1
TYPE POST.TXT > LPT1
(Control-Z)
```

#### Step 6 - Change LaserWriter II to LaserJet+ emulation mode

-----

Type HPMODE from the DOS prompt to set the LaserWriter IINTX to LaserJet+ emulation. The printer will internally switch from the PostScript Batch mode to LaserJet+ emulation, and, after a few seconds, it will print a test page displaying the new settings.

Your printer will now print graphics and text properly with the emulation provided by the Adobe PostScript ROMs. This fixes the problem of losing the eighth data bit for special text and graphics. This also fixes the problem of the "print screen" keyboard command not functioning.

#### Article Change History:

23 Feb 1995 - Added PostScript caution and reformatted.

## LaserWriter IINTX: Printing in HP Emulation Mode (Part 2 of 3)

Revised: 3/4/90  
Security: Everyone

LaserWriter IINTX: Printing in HP Emulation Mode (Part 2 of 3)

=====

This article last reviewed: 23 May 1989

Part 2 covers troubleshooting your setup for printing in HP emulation mode. (Part 3 covers the upper 128 ASCII characters for HP LaserJet Plus emulation.)

### Troubleshooting

-----

LaserWriter II will not print test page to indicate HP emulation mode:

Check cable connections to and the paper supply for the LaserWriter II. Turn off any spooler commands that may be running on the PC.

Check the PostScript file (POST.TXT) and the batch file (HPMODE.BAT) for any typing errors. If none is apparent, try retyping the PostScript code from scratch. If the LaserWriter II does not receive the PostScript code character-for-character, the mode change will not work.

Once the code has been retyped, send it to the LaserWriter II. If the LaserWriter II prints a test page, then all is well. If the LaserWriter II prints a page containing the PostScript code, it is in LaserJet+ emulation mode, but a test page will not be printed (there is an error in the PostScript code that instructs the LaserWriter II to print a test page, but the mode switch was successful). If the LaserWriter II does nothing, then start over from step 1.

LaserWriter II will not print from within an application:

Check the application's print settings to ensure that it is sending output to LPT1 or COM1. The application also must be set up to print to a LaserJet+ using Times, Helvetica, or Courier.

NOTE: When printing from DOS, always follow the print command with a "Control-D". A "Control-D" tells the LaserWriter II that the data transmission is complete and that printing can now begin. The best method

is to create another text file with a "Control-D" inside.

Enter the following from the DOS prompt:

```
COPY CON D.TXT
(Control-D)
(Control-Z) or (F6)
```

Now, make a batch file to send the end-of-page marker to the printer. From the DOS prompt, enter:

```
COPY CON END.BAT
TYPE D.TXT > LPT1
(Control-Z) or (F6)
```

After doing a TYPE or Print Screen or DIR to the printer, just type END, and the printer will print any remaining data in the buffer.

If your print job does not have a Control-D (end-of-page) character, you must wait for your print job until a timeout, or until another job is printed that is larger than a page.

Printing to a LaserWriter IINTX in HP LaserJet Plus Emulation Mode Via AppleTalk from an MS-DOS Computer

---

#### 1) Connection:

Connect a LocalTalk connector box to the appropriate port on the PC (an AppleTalk interface card must be installed inside the PC). Connect another LocalTalk connector box to the LaserWriter II. Using a LocalTalk cable, connect the two connector boxes together.

Note: If more devices are to be added to the AppleTalk network, consult the manual that came with the LocalTalk cables and connectors.

#### 2) Switch Settings:

While the LaserWriter IINTX is off, set the printer DIP switch settings to:

- 1) UP
- 2) UP
- 3) DOWN
- 4) DOWN
- 5) UP
- 6) UP

These switch settings place the LaserWriter IINTX in:

HP LaserJet Plus mode  
LocalTalk

3) Power On:

Turn on the LaserWriter IINTX and the PC. After a few seconds, the LaserWriter II will print a test page containing its current settings (listed above).

4) Using AppleShare PC, connect to the LaserWriter IINTX on the AppleTalk network. Set the LaserWriter for PostScript mode. This lets the ASCII characters from the PC be passed to the LaserWriter IINTX across LocalTalk.

5) Print to the LaserWriter IINTX as if it were directly connected to the LPT port selected in AppleShare PC.

Currently, there is no available method of software-switching back to PostScript or any other emulation mode once leaving the PostScript mode. The correct method is to change the DIP switch settings and wait 30 seconds. If PostScript is desired, switch 1 should be set to the DOWN position. Wait 30 seconds and place the switch back to the UP position.

## Apple IIGS Game Port Information

Revised: 8/4/89  
Security: Everyone

Apple IIGS Game Port Information

=====

This article last reviewed: 23 June 1989

Some questions have been raised as to whether one should attach a third-party device to the Apple IIGS game port that directly supplies +5 volts to the port and does not have a resistor for limiting voltage to the port. People fear that additional voltage without a resistor might short the logic board.

The truth is that even if the third-party device is actually shorting the logic board, it would not necessarily be caused by the lack of a current-limiting resistor.

Applying +5V through the device to the game port is not a problem, because the game port has +5V on it already. However, because the inputs from the game port go directly to a TTL device, voltages greater than +5V should not be applied to the port.

Joysticks and game paddles have a 270-ohm resistor connected from ground to the "Normally Open" side of the pushbutton switch. The "Normally Closed" side of the switch goes back to the game port, then to the logic board, and also to Signal Ground. This resistor limits the amount of current drawn from the power supply by closing the switch. It does not limit the current going back to the game port.

## AppleTalk Network Problem and Fix: A Case Study

Revised: 8/4/89  
Security: Everyone

AppleTalk Network Problem and Fix: A Case Study

=====

This article last reviewed: 23 May 1989

This article describes a problem with a school lab network and how the problem (after two attempts) was solved. The network has a PhoneNET backbone of 2100 feet with a repeater in the middle. Workstations include 25 Apple IIe systems, 3 Macintosh systems, 1 Apple IIGS, a few AppleTalk ImageWriter II printers, and one AppleTalk ImageWriter LQ printer. Devices are connected off of the backbone with RJ-11 jacks/wires as small trunks.

In the diagrams below, nodes (jack boxes on backbone) are the numbers 1 through 22. R denotes a Farallon repeater. "f.s." denotes a Macintosh SE with HD20 SC File Server.

```
1-2-3-4-5-6-7-8a=R=8b-9-10-11-12-13-14-15-16-17-18-19-20-21-22
      |
      f.s.
```

The problem was that prior to installation of the repeater, various Apple IIe systems would only intermittently be able to start up off of the server ("f.s." located at node 7); particularly, those toward the ends of the backbone.

### Solution #1: Adding a Repeater

-----

A repeater was installed by separating node 8 into 2 nodes (8a and 8b) and placing the repeater between the two nodes. While installing node 8, the engineer noticed a loose, but electrically continuous connection, within the RJ-11 box. Thinking nothing of it, he installed the repeater and tightened the screws. All worked great--everyone gave all of the credit to the repeater (Farallon had said, all along, that we shouldn't need one with only 2100 feet of backbone. We had to try something, so we bought one.)

4-5 Weeks Later

-----

A teacher's class was disrupted by a loud "popping" noise from an Apple IIe in her classroom. The screen inverted, became garbled, and returned to normal. Coincidentally, the network quit working, and machines could no longer start up on the network--everything went back to the way it was four or five weeks earlier.

This was too much of a coincidence and pointed to the repeater. (All the board, computer, and ohmmeter checks of the backbone tested fine.) Furthermore, after taking out the repeater, the engineer got a few more of the machines to start. All the machines within 700 feet of the repeater and the file server started up regularly.

After many hours of lost labor time and much frustration, the engineer took the only approach that he could think of to narrow down the cause of the problem; he asked for a replacement repeater. But once installed, there was no change. Additional tests, inspections, ohm checks, continuity checks, and termination checks failed to give a clue.

#### Solution #2: Damaged, Loose Wiring

-----  
Although the engineer had been warned repeatedly to make sure that there were no extra resistors on the network, after seeing the ohmmeter readings of the backbone, he defied logic and put another 100-ohm resistor where the highest resistance measurement was taken (node 15: 80.1 ohms with the repeater installed). The result: five more machines came up (nodes 16 through 20).

He decided to put in another resistor (maximum of four, now), and there was no further change. This came as a surprise, because node 20 now started with lightning speed (it was sluggish before), while node 21 just sat there looking "dumb." That's when it was clear that it was time to crawl along the wires again to see what was going on.

The loose wire idea came up, so an inspection was made of node 21. There it was. The pair of wires coming into the box (#21) had been damaged to the point that they were "broken" but not fully severed. This pair had been all but fully separated from the wiring posts. This fit the confusing symptoms of passing the ohmmeter checks, but possibly causing data reflections in an AC mode setting. After reconnecting the wires, all was fine. (Reflection checks still passed the requirements.)

The installation at the box did not have a complete plastic molding installed to protect the wires from the young students' feet. The wire had been kicked and stretched to the breaking point. A plan for molding installation is in the works.

The extra resistors were removed; everything worked fine, but a little slower on the ends. One resistor was placed at the high-resistance point again (node 18) with the result that the end units start up very fast (as if they were next to the server).

In retrospect, it appears that the repeater was not needed in the first place. Its installation could have been avoided if the wires had been

tightened. (Reminder: ohmmeter checks can still test okay on bad or loose connections. It's the AC component, the +5V and -5V, that counts). However, the school is planning to add a new lab to the network and will eventually need the repeater anyway.

It appears that all of the other coincidences were merely coincidences. Most likely, a power surge occurred that disrupted the computers. The cable could have been kicked even before the surge, because the low traffic on the network at the time may have caused it to go unnoticed).

## **LaserWriter IINT/NTX: How To Print Font Samples**

Revised: 3/4/90  
Security: Everyone

LaserWriter IINT/NTX: How To Print Font Samples

=====

This article last reviewed: 23 May 1989

On the disks that come with the LaserWriter II printers is a program called "LaserWriter Font Utility." This program prints a sample of all fonts (in 12-point) in the LaserWriter and/or the hard disk attached to a LaserWriter IINTX. If you want to print the available fonts in multiple sizes, it is necessary to create your own font sample document.

Security: Everyone

Macintosh IIcx: Some NuBus Cards Don't Fit

=====

Article Created: 23 May 1989  
Article Last Reviewed: 10 July 1992  
Article Last Updated:

TOPIC -----

Does the smaller form factor of the Macintosh IIcx affect the size of NuBus cards? In other words, will cards designed for the Mac II fit inside a IIcx?

DISCUSSION -----

There are two NuBus cards that have problems fitting in a Macintosh IIcx. Both are video cards: the SuperMac Spectrum 8-bit color card and Truevision NuVista 24-bit color card. Apple has been unable to verify whether or not the DCA MacIrma card fits properly in the Macintosh IIcx. We will try to provide more information as it becomes available.

Note: Any NuBus card designed to the physical specifications published by Apple will fit properly in a Macintosh IIcx.

ImageWriter II: How To Print From Applesoft BASIC Over A Network

=====

This article last reviewed: 23 May 1989

To print to an ImageWriter II over a network using Applesoft BASIC follow this procedure:

- 1) Ensure that you have run the Chooser II to select the printer that you want to address.
- 2) This code can be used to allow Applesoft BASIC to communicate with the chosen ImageWriter II:

```
10  D$=CHR$(4)
20  Print D$; "PR#7"
30  Print "Hello Printer"
40  Print D$; "PR#0"
50  End
```

## A/UX: Cray Connectivity (6/93)

Revised: 8/12/93  
Security: Everyone

A/UX: Cray Connectivity (6/93)

=====

Article Created: 23 May 1989  
Article Reviewed/Updated: 25 June 1993

TOPIC -----

This article describes alternative solutions for A/UX to Cray connectivity.

DISCUSSION -----

In general, A/UX 3.0 is a full implementation of AT&T System 5.2.2 (with Berkeley 4.3 extensions) UNIX Operating System. It is capable of multi-users and multitasking environments. It also provides many defacto standards, including TCP/IP communications protocol, Network File System (NFS) from Sun Microsystems, Berkeley networking services, and X Window System from MIT. As a result, A/UX can talk to almost any machine that any UNIX machine talks to. Here are some connectivity examples:

### Ethernet Connection

-----

If the remote machine (Cray) supports TCP/IP Ethernet, regardless of the type of operating system Cray is running, A/UX can talk to it via "telnet" or "rlogin" and use "ftp" for file transfer.

If the remote machine supports NFS, then either A/UX or the remote machine can be configured as an NFS server or NFS client.

If the remote machine supports X Window System, then both A/UX and the remote machine can run X server and/or X client applications on different displays, so that the two machines to share resources.

### Serial Line Connection

-----

A/UX supports two internal RS-232 serial ports for connecting to any RS-232 devices, like modems, regular terminals, and printers, hard-wired to another computer's RS-232 ports (PC, VAX, Cray, and so on). You can use "cu", "tip", or "kermit" (provided in A/UX) to connect your A/UX to the

remote machine.

Since A/UX 3.0 (as did previous versions) supports SLIP (Serial Line Internet Protocol), if the remote machine also supports SLIP, SLIP might be another solution for doing remote connection and file transfer by using the underlying Internet network services, such as "rlogin", "telnet", "rcp", and "ftp".

## MacDraw 1.9.5 & 1.9.6/LaserWriter 5.2 Conflict: Workaround

Revised: 12/6/89  
Security: Everyone

MacDraw 1.9.5 & 1.9.6/LaserWriter 5.2 Conflict: Workaround

=====

This article last reviewed: 23 May 1989

This article describes a workaround for the conflict between MacDraw versions (1.9.5 and 1.9.6) and LaserWriter 5.2: If you get a system bomb when printing from MacDraw, try this:

- Select All
- Group
- Print
- Ungroup

This seems to eliminate system bombs and keeps you from having to "downgrade" the LaserWriter drivers across the network.

(Be careful when you ungroup after printing--click on an object to deselect the selected objects, or you accidentally can move all the objects in your document.)

## MacLink Plus: AFE-Compatible File Translation

Revised: 8/4/89  
Security: Everyone

MacLink Plus: AFE-Compatible File Translation

=====

This article last reviewed: 26 May 1989

Some users have had problems with MacLink Plus from DataViz, Inc.; it doesn't work well with Apple File Exchange (AFE) and the Apple 5.25-inch drive. The reason is that earlier versions of MacLink Plus were created before these products were developed.

Prior to the introduction of AFE and the Apple 5.25-inch drive, the earlier versions of MacLink Plus were one of the few file transfer and conversion utilities for moving files between the PC and Macintosh. However, with the introduction of AFE, DataViz diversified its product line by introducing additional translators for AFE. The DataViz AFE translators should fulfill your customer's needs. They also support the Apple 5.25-inch drive.

MacLink Plus/translators v2.12 includes a library of over 46 different translation combinations that extend the translation capabilities of the Apple File Exchange utility. It provides automatic conversion of a file format and contents between a variety of normally incompatible applications.

Users with a number of PCs and Macintoshes should investigate connecting them via LocalTalk and then mounting the files to the desktop using TOPS.

For more details, search the Tech Info Library under "DataViz" and/or "TOPS".

## Apple III: Converting Three Easy Pieces Files to Macintosh

Revised: 8/20/89  
Security: Everyone

Apple III: Converting "Three Easy Pieces" Files to Macintosh

=====

This article last reviewed: 2 August 1989

TOPIC -----

Is there a way to transfer files from the Apple III package "Three Easy Pieces" to an application on the Macintosh?

DISCUSSION -----

Using an Apple File Exchange (AFE) translator, Three Easy Pieces files can be converted into Microsoft Works files for the Macintosh.

Transfer the files from the Apple III onto a 3.5-inch disk -- use either an Apple IIe or Apple IIIGS running AppleWorks. Read the files into AppleWorks from the 5.25-inch drive and save them to the 3.5-inch drive.

The Works-to-Works translator for Apple File Exchange moves files from AppleWorks into Microsoft Works, as long as the files are on a 3.5-inch disk and in the ProDOS format, since ProDOS and SOS formats are compatible.

## Apple II Family and Chooser: Frequently Asked Questions (12/95)

Revised: 12/1/95  
Security: Everyone

Apple II Family and Chooser: Frequently Asked Questions (12/95)

=====

Article Created: 8 August 1989  
Article Reviewed/Updated: 1 December 1995

TOPIC -----

This article contains frequently asked questions (FAQ) on the Apple II computer and the Chooser.

DISCUSSION -----

Question: When I choose a printer is the choice saved on disk so that I do not need to use Chooser again?

Answer: Yes, the Chooser selection is saved to disk as the user exits Chooser.

Question: When I choose a printer do I need to use Chooser each time?

Answer: You do not need to use the Chooser each time you print. The Chooser is used only when changing printers.

Question: If the choice is saved is it saved on the current startup disk or on the disk Chooser resides on?

Answer: The printer choice is saved to the disk with Chooser on it.

Question: If the choice is saved is it saved only if the disk Chooser resides on is the current startup disk?

Answer: The choice is saved to the Chooser disk no matter where Chooser resides.

Question: If an AppleShare user who starts up over the network does not have a

default printer assigned from the server, will their most recent choice be saved after powering down?

Answer: The last choice is saved as the user exits Chooser.

Question: If an AppleShare user who starts up over the network does not have a default printer assigned from the server, where is it saved?

Answer: This choice is saved on the server from which Chooser is run.

Question: Is there any difference in these characteristics between the Apple IIe and the Apple IIGS?

Answer: There are no differences between an Apple IIe and an Apple IIGS in these matters. The Chooser program is the same on both computers.

NOTE: The user's Chooser selection overrides the Server Admin default printer assignment.

ADDITONAL NOTE: GS/OS 5.0 uses the Control Panel for network choices. If GS/OS 5.0 is being used, the Chooser program is no longer needed.

## Apple IIGS: How To Print to Local & Network Printers

Revised: 8/20/89  
Security: Everyone

Apple IIGS: How To Print to Local & Network Printers

=====

This article last reviewed: 8 August 1989

TOPIC -----

Is it possible to print to local printers from an Apple IIGS on an Apple II network?

The network in question has an Apple IIGS and an ImageWriter II in each work area. Each of these Apple IIGS systems is networked into a central office where they share a LaserWriter IINTX. Sometimes users need to print to the local printer, other times to the LaserWriter.

Can they do this while on the network without shutting down their machines and restarting with software locally? They are using network versions of AppleWorks with third party applications and E-mail.

DISCUSSION -----

Printing both locally and over the network depends on the application's method of selecting a slot for printing.

AppleWorks does provide a method for assigning a printing slot, allowing three printers to be defined in the Printer Information screen. To do this:

- 1) Set up the printer specifications for the local ImageWriter printer in slot #1.
- 2) Set up an ImageWriter printer for slot #7. (This is for the ImageWriter Emulator used in the LaserWriter.)
- 3) Choose the desired printer by going to the Main Menu/Other Activities/Printer Information screen and selecting a new Open-Apple-H printer.

If the third party programs allow a slot choice within the program, select slot #1 for the local printer and slot #7 for the network printer.

Prior to using a slot #7 printer (the network printer), use the Chooser application to select the appropriate network printer.

(NOTE: These descriptions assume the use of the printer port on the Apple IIGS.)

## DECmate III-to-Macintosh Connectivity

Revised: 8/20/89  
Security: Everyone

DECmate III-to-Macintosh Connectivity

=====

This article last reviewed: 8 August 1989

TOPIC -----

Can documents can be transferred from a Macintosh connected to a DECmate III running CP/M-80?

DISCUSSION -----

A DECmate III running CP/M-80 should have no difficulty moving ASCII text files to a Macintosh. As with the DECmate I and DECmate II, a serial connection is made between the DECmate and the Macintosh. This connection can be a direct machine-to-machine connection with a null modem cable, or a modem-to-phoneline-to-modem connection.

The XMODEM file transfer protocol was originally developed for the CP/M operating system. Nearly all of the CP/M communication programs provide support for the XMODEM protocol. Most Macintosh programs also support the XMODEM file transfer protocol. By running applications supporting XMODEM on both computers, a file transfer can be accomplished.

## AppleShare: Set Apple IIGS Startup Slot to 7 To Boot

Revised: 8/20/89  
Security: Everyone

AppleShare: Set Apple IIGS Startup Slot to 7 To Boot

=====

This article last reviewed: 8 August 1989

TOPIC -----

What setting do I use in the AppleShare startup slot on an Apple IIGS?

I have been told that when setting the slots for an Apple IIGS AppleShare workstation the startup slot should be set to "Scan". Others have told me that startup slot should actually be set to 7. Which is correct?

DISCUSSION -----

Since a Scan operation starts at slot 7 and works down the slots until reaching slot 1, setting the startup slot to "Scan" can work. If the ProDOS-prepared server is available as the Apple IIGS starts up, the booting takes place from the server.

However, should the server be unavailable as the Apple IIGS starts up, AND a startup disk is in an attached disk drive, booting takes place from that disk drive.

If booting only from the server is desired, then it is probably a good idea to set the startup slot to 7 to ensure that the boot process ONLY works across the network.

## GS/OS 5.0 AppleShare Access Over Network Bridge

Revised: 9/22/89  
Security: Everyone

GS/OS 5.0 AppleShare Access Over Network Bridge

=====

This article last reviewed: 8 August 1989

TOPIC -----

Does GS/OS 5.0 allow access to an AppleShare File Server through a bridge on the network?

DISCUSSION -----

GS/OS 5.0 does provide network file services to an AppleShare File Server over bridges. This feature works like the Apple IIGS System Disk 3.1 or 3.2.

However, GS/OS 5.0 has the same limitations for network startup that exist with System Disk 3.1 or 3.2: network startup must take place within the physical network -- not across a bridge.

HayesConnect 1.0C: Corrects Hang Problems of 1.0B

=====

This article last reviewed: 9 August 1989

TOPIC -----

I have a problem running the Hayes Modem serving software on our AppleShare File Server. Here is the configuration:

Server: Macintosh IICx with 4MB RAM  
Software: AppleShare 2.0.1  
Timbuktu 2.0.1 f2  
HayesConnect 1.0B

The system hangs in AppleLink and in MacTerminal communications. The server also hangs and has to be reset. Why?

DISCUSSION -----

The problem is probably with HayesConnect, version 1.0B. Contact Hayes Technical Support group for an update to HayesConnect 1.0C, which should correct this problem.

## A/UX: Printing to LaserWriter IINT From AT&T 3B2 (1/96)

Revised: 1/25/96  
Security: Everyone

A/UX: Printing to LaserWriter IINT From AT&T 3B2 (1/96)

Article Created: 8 August 1989  
Article Reviewed/Updated: 25 January 1996

TOPIC -----

I am having a problem printing to a LaserWriter IINT from an AT&T 3B2 workstation.

I want to print from an AT&T 3B2 running System V Release 2. There are no extensions (Berkeley or otherwise), and there are no Macintoshes and no network involved in this configuration. I can "cat" a PostScript file through a port to the LaserWriter IINT without problems.

When I "lp" the file through the standard AT&T spooler and the same port, the LaserWriter IINT green light flashes for several minutes (about 3 to 5 minutes beyond what the cat takes). The green light eventually goes to steady state without printing anything. A check of the queue indicates that it was printed without error; however, there is no output.

I eliminated: the cabling, XON/XOFF, data/start/stop bits, parity, the PostScript file, the history of the LaserWriter IINT and the EEROM being set incorrectly, and also the returned Control-D (EOF) somehow interfering as the problem. There are no error messages or adverse log indications. I am now at 1200 baud to remove some possible problems associated with using 9600 baud.

I checked the output of the port between the cat and the LaserWriter IINT. It appears that the LaserWriter IINT is adding or changing something. I do not know exactly what because of the method used to observe and the lack of time to set up for another (and more revealing) test. I can say that it is different, and I assume this should NOT be the case.

What I don't know is:

- 1) Has anyone successfully connected the LaserWriter IINT to a 3B2 with a vanilla AT&T System 5 "lp" spool/queue (no Berkeley extensions)?

- 2) How does their queue script read? Can I get a copy?
- 3) What is there about a standard lp queue that could add to or alter the contents of a PostScript file passing through?

DISCUSSION -----

A/UX is AT&T System V Release 2 -- the same as the customer's AT&T 3B2 system. If something works for the A/UX system, there should be a way to make it work with the AT&T 3B2. Apple has successfully connected LaserWriter IINTs to A/UX systems and used the A/UX lp print spooler. A/UX does not use the Berkeley extensions for printing.

When printing to a PostScript device, A/UX uses a script located in /usr/spool/lp/model/psinterface. The script used by the 3B2 should be similar, if not identical, to the A/UX version.

The PostScript file going to the printer must have a first line that begins with:

```
%!PS-Adobe-
```

or the LaserWriter IINT won't know what to do with it. Since using cat to send the file directly to the printer works fine, we can assume that the original file is OK and that the connection between the computer and the printer is good.

An error is most likely to be introduced when the psinterface script assigns a magic number to the file being printed. Normally, the magic number for a file is derived from the first few characters of the file, which are then matched against the /etc/magic file to return some information about the contents of the file.

However, the psinterface script assigns its own magic number to the file being printed. Psinterface cuts the first eleven characters from the file to be printed and uses a case statement to assign a magic number to the file. Depending on what that magic number is, psinterface does something different with the file.

In the A/UX version of psinterface, this section of the script reads as:

```
case "$magic" in
%!PS-Adobe-) rev=1 ;;
```

Check the 3B2 version of the script and see if these lines match. If they don't, try changing the 3B2 version to match the A/UX version.

## LocalTalk PC Card: Available for MS-DOS, Not OS/2

Revised: 8/20/89  
Security: Everyone

LocalTalk PC Card: Available for MS-DOS, Not OS/2

=====

This article last reviewed: 8 August 1989

TOPIC -----

I want to place PCs running OS/2 on an LocalTalk network. Are there any LocalTalk network PC cards that support OS/2 at this time?

DISCUSSION -----

Apple is unaware of any AppleTalk network PC cards with drivers for OS/2. The AppleTalk network PC card software from Apple contains only MS-DOS drivers.

DayStar Digital makes a MicroChannel version of an AppleTalk network PC card for PS/2 machines, but again, the DayStar card includes only MS-DOS drivers, not OS/2 drivers.

While either of these cards can be placed in an OS/2 system, the cards will be functional only under MS-DOS, since the accompanying software lacks the drivers for OS/2.

AppleShare: Virus Can Attack Only User-Write-Accessible Volume

=====

This article last reviewed: 9 August 1989

TOPIC -----

Here are two questions about AppleShare volumes and viral infections.

DISCUSSION -----

Q) If I partition a server hard disk into a read-only volume and a read-write volume, is it possible for the read-only volume to become infected if the read-write volume becomes infected?

A) No, a virus can attack only folders and files to which the user of the infected program has write access privileges.

Q) If I did some administrative work on the read-only volume -- that is, launched applications that made it write-able under the administrator account -- could a virus infect the volume that was once write-protected?

A) Yes, since the Administrator has write access privileges, so would the virus.

LaserWriter Driver 6.0: Defaults to Color

=====

This article last reviewed: 9 August 1989

TOPIC -----

I am using the new (v6.0) LaserWriter drivers with QMS printers. Printer options default to color/grayscale under these drivers (as opposed to black and white). This seems to slow printing. Is there any way to change this default?

DISCUSSION -----

The primary focus for the LaserWriter 6.0 driver is color printing. This is why the color option is the default setting. There is currently no way to change the default setting to black and white.

## Macintosh-to-Modem Pool Through Rolm Phone System

Revised: 6/18/92  
Security: Everyone

Macintosh-to-Modem Pool Through Rolm Phone System

=====

Article Created: 9 August 1989  
Article Last Reviewed: 18 June 1992  
Article Last Updated:

TOPIC -----

This article tells how to cable a Macintosh from a Rolm phone system to access a modem pool.

DISCUSSION -----

If you want to use a Macintosh from a Rolm phone system and access a modem pool on the switch, you need to provide DTR from the Macintosh. The standard cables do not provide this. You need to make a special cable with the following pinouts to provide the appropriate signalling:

| DB-25 | to | DB-9 |
|-------|----|------|
| ----- |    | ---- |
| 1     |    | 8    |
| 2     |    | 5    |
| 3     |    | 9    |
| 7     |    | 3    |
| 20    |    | 6    |
| 8     |    | 7    |

Use a standard DB-9-to-DIN-8 cable to connect to the Macintosh.

## Macintosh II High-Resolution Video Card: New Features

Revised: 8/20/89  
Security: Everyone

Macintosh II High-Resolution Video Card: New Features

=====

This article last reviewed: 10 August 1989

TOPIC -----

This article describes the new features of the Macintosh II High-Resolution video card.

DISCUSSION -----

The Macintosh II High-Resolution Display Video Card is the cost-reduced replacement for the previous 4- and 8-bit Macintosh II Video Card (M0211 and M5640). This new card is sold in 4- and 8-bit configurations (M0322 and M0324, respectively).

This new release is fully compatible with the previous card when used with Apple's video drivers, monitors, and cable. Applications that make direct hardware calls may not work with the revised card. Also, third-party video cables may need to be changed (see item 2 below).

New Features  
-----

The following minor features were added to the card. They should not have a major impact on the typical use of these cards.

### 1. Monitor Type Detection

At startup, the High-Resolution Display Video Card senses the monitor type by sensing a previously unused signal line: pin 4 in the D-15 video connector. The selection is as follows:

|          |                                |
|----------|--------------------------------|
| SENSE 0  | Monitor Type                   |
| (Pin 4)  |                                |
| 1 or N/C | NTSC Timing RGB video out      |
| 0        | 12- and 13-inch Monitor Timing |

(Note: Some third-party cables may not be wired correctly to support this detection scheme.)

## 2. New Driver Level Control of RS-170 RGB Video

The card supports two RGB interlaced video resolutions:

- 512 by 384 pixel (default mode) and
- 640 by 480 pixels

To select the higher resolution, the system needs the new Monitor CDEV and Slot Manager supplied with the 32-bit QuickDraw, plus the correct cable configuration (see item 1). Selection is made by choosing the monitor icon (highlighted borders) connected to the Macintosh II High-Resolution Video Card and clicking on the Options button. A dialog box will appear with the options.

In addition, the card only produces RGB interlaced video in the 4- and 8-bit mode.

## 3. Enhanced Firmware

In addition to the scanning modes mentioned above, the card supports uncorrected gamma, has an integrated gamma directory, and implements a new set of driver calls to support these new features.

## MacAPPC and MPW 3.0: Compatibility Issues

Revised: 8/20/89  
Security: Everyone

MacAPPC and MPW 3.0: Compatibility Issues

=====

This article last reviewed: 1 August 1989

TOPIC -----

This article discusses the compatibility of various versions of MacApp and MPW.

DISCUSSION -----

MacApp 1.1.1 programmers should use MPW 2.0.2. Apple does NOT support developing with MacApp 1.1.1 under MPW 3.0.

MacApp 2.0b5 was designed for use under MPW 2.0.2. It is possible to tweak MacApp 2.0b5 to run with MPW 3.0, but this is also an UNSUPPORTED solution.

MacApp 2.0b9 does NOT support MPW 2.0.2, but DOES support MPW 3.0.

## AppleTalk Internet Router

Revised: 8/21/89  
Security: Everyone

AppleTalk Internet Router

=====

This article last reviewed: 19 June 1989

TOPIC -----

This article gives general information on the AppleTalk Internet Router. It includes common questions with answers.

DISCUSSION -----

The AppleTalk Internet Router is a software router that interconnects AppleTalk networks, including LocalTalk, EtherTalk, and TokenTalk networks, to form an AppleTalk internet. The router moves data from one network to another transparently, so the internet functions like a single network. This means that users access file, print, and mail resources across the internet in the same way they access these resources on a single network.

The AppleTalk Internet Router is fully compatible with AppleTalk Phase 2. As specified in the AppleTalk Phase 2 protocols, you can use the AppleTalk Internet Router to assign a range of network numbers and a list of zone names to a single EtherTalk or TokenTalk network.

The AppleTalk Internet Router has four main purposes:

- It connects two to eight networks, allowing users access to services on other networks. The connected networks can be LocalTalk, EtherTalk, or TokenTalk networks.
- It isolates traffic on different parts of an internet. Although AppleTalk Phase 2 supports very large, single AppleTalk networks, performance can be improved by using a router to break up such a network. The router isolates local traffic and passes traffic onto the internet only when necessary.
- It creates zones that conceptually partition the internet, so that users can more efficiently access shared services.

- It enlarges a network that has reached its maximum length or number of devices. The number of devices per network is an issue for LocalTalk networks. The maximum length is an issue for LocalTalk networks and thin Ethernet networks.

The AppleTalk Internet Router runs on the Macintosh Plus, SE, SE/30, and Macintosh II family of computers. It runs transparently in the background of other processes running on the same system. You can run the router on a machine that is also running the AppleShare File Server, the AppleShare Print Server, and various electronic mail servers. To run the router on the same machine as one or more servers, you must have 2MB of memory.

The AppleTalk Internet Router ships with the "AppleTalk Internet Router Administrator's Guide". The guide has complete information on how to set up the router, when to create an internet, how to plan the physical layout, where to place a router, when to use a backbone network, and so on. It also gives advice on network numbering and zone names. Observing certain guidelines in identifying networks can help maintain order as the internet grows.

The AppleTalk Internet Router also ships with a document titled "AppleTalk Phase 2 Introduction and Upgrade Guide". This booklet describes AppleTalk Phase 2 for the lay person and describes how to upgrade an AppleTalk internet to Phase 2.

The Upgrade Utility will be packaged with the AppleTalk Internet Router for a limited period. The Upgrade Utility permits AppleTalk Phase 2 and Phase 1 routers to operate on the same internet. Upgrading an AppleTalk internet to Phase 2 requires that all routers be upgraded to Phase 2 versions. However, it may not be feasible for customers with very large internets to upgrade all their routers at once. For this reason, Apple has written the Upgrade Utility that runs in the background of the AppleTalk Internet Router and enables that router (and its connected networks) to be part of an internet on which 1.0 routers still exist.

The Node Identification Utility also ships with the AppleTalk Internet Router. It enables you to determine which nodes on an internet have been upgraded to AppleTalk Phase 2.

Customers must buy a copy of the AppleTalk Internet Router for every machine that will run the software. Site licenses will not be available.

#### Questions and Answers on the AppleTalk Internet Router

-----  
Q. Does the AppleTalk Internet Router support TCP/IP or DECnet routing?  
A. No. The AppleTalk Internet Router supports routing of AppleTalk protocols only. It can be run in parallel with a second non-Apple router that supports other network protocols.

Q. How many networks can be interconnected with the AppleTalk Internet Router?

A. The AppleTalk Internet Router allows from two to eight networks to be interconnected. By exchanging information with other routers on the internet, the AppleTalk Internet Router can learn about 1024 other networks in the internet. Each of these 1024 networks can contain multiple AppleTalk Phase 2 "virtual networks."

Q. How many zone names can I assign to one EtherTalk or TokenTalk network?

A. 256.

Q. How can I configure eight networks on the AppleTalk Internet Router?

A. You need to use a Macintosh II or IIX that handles up to six network cards and the two LocalTalk ports to be used by the router. You can use the router without a video card or monitor. To administer such a router, you can use the Timbuktu product from Farallon.

Q. Does the router degrade the performance of the AppleShare File Server or Print Server when run in the background?

A. Yes. The amount of degradation depends on the traffic passing through the router. Typically the router has to be extremely busy to noticeably affect server performance.

Q. Because the AppleTalk Internet Router is a Phase 2 router, will third-party router manufacturers need to upgrade their routers to communicate with Apple's router?

A. Yes. Apple has worked very carefully with all the major third-party router manufacturers. All of them plan to offer Phase 2 upgrades to their products.

## Coax/Twinax Card: Product Information (8/94)

Revised: 8/3/94  
Security: Everyone

Coax/Twinax Card: Product Information (8/94)

Article Created: 19 July 1989  
Article Reviewed/Updated: 3 August 1994

TOPIC -----

This article provides a description of the Apple Coax/Twinax Card.

DISCUSSION -----

### Overview

-----  
The Coax/Twinax card is a 9-inch NuBus hardware product. The card is based on the National Semiconductor 8344 LSI chip, which provides the encode/decode of Coax Type A and Twinax cable signals. The chip supports full 3270 data streams for Control Unit Terminal(CUT) and Distributed Function Terminal(DFT) operations. The Twinax portion supports all 5250-type devices. (See the "Special Information" section at end of this article).

### Apple Coax/Twinax Card

-----  
The Apple Coax/Twinax card uses the MCP card foundation with additional add-in components to provide coax encoding and decoding of coax commands. The encoder/decoder is National Semiconductor's NC 8344. The Motorola 68000 found on the MCP card manages the terminal session's 3270 presentation space and handles the API calls. The 500K RAM space is used to maintain 68000 code, 8344 code, and the presentation spaces.

The System software required to operate the Coax/Twinax card is the multitasking MCP/OS referred to as A/ROSE and the 3270 CDEV. There are no switches to set on the card. The card's self-test indicates pass/fail based on the status of two LEDs on the card edge. Green indicates the card is OK and Red indicates the card has failed the on-board diagnostic.

### Special Information

-----  
SNA•ps 3270 software does NOT emulate 5250 terminals even though the hardware

MCP card has that capability. It does include support for CUT and NLCA connections on the Apple Coax/Twinax Card. Andrew Corporation provides a product called MacMidrange which provides 5250 terminal services and operates on the Apple Coax/Twinax Card.

Article Change History:

03 Aug 1994 - Update article with SNA•ps 3270 rather than MacDFT and Andrew's MacMidrange product.

## HyperCard: How To Determine HyperCard Field Line Count

Revised: 6/24/90  
Security: Everyone

HyperCard: How To Determine HyperCard Field Line Count

=====

This article last reviewed: 26 May 1989

On occasion, HyperCard programmers need to know how many lines are in a field. There are two ways of looking at this question. One is how to determine the number of display lines in a field due to word wrap. The other thing you might want to know is how many return characters are in a field. HyperCard tells you this, if you ask how many lines are in the given field. The question of how many display lines are in a field is a bit more difficult. The script at the end of this article can get this information for you.

The script works by taking the given field, changing it to a scrolling field (if it isn't already), and then making the height of it the smallest multiple of the size of the text height greater than 50 pixels. This is done because the next step it does is to scroll from the top of the field to the bottom. If field is not at least 50 pixels high, it will not scroll.

Once HyperCard has scrolled to the bottom of the field, it can tell you how much text has been scrolled off. With this information, the size of the window, and the height of the text, you can calculate the number of lines.

The height of the field is made smaller, because if the visible field is not filled enough to scroll, there is no way to determine how much of the field (number of lines) has text in it. However, as stated above, the field also has to be tall enough to scroll. The combination of these two requirements means that the script below can determine the number display lines, if that number is greater than 3. If there are less than three lines, it tells you there are 3, anyway. Here's the script:

```
on mouseUp
  put empty
  lock screen
```

```
put the style of fld test into holdStyle
-- so you can reset the style
```

```
    get the rect of fld test
    put it into holdRect
    -- so you can reset the rect

if the style of fld test does not "scrolling"
then
    set the style of fld test to "scrolling"
    add 15 to item 3 of it
    -- to account for the scroll bar
end if

set the scroll of fld test to 0
    -- get to the top
put (item 2 of the rect of fld test + 50) into item 4 of it
    -- make the field as small as possible to account for small amounts
    -- data and still scroll
set the rect of fld test to it

drag from item 3 of the rect of fld test - 8,item 2 of the rect of
fld test + 20 to item 3 of the rect of fld test - 8,item 4 of
the rect of fld test - 20
    -- grab the thumb and drag to the end of the field

put the scroll of fld test + (item 4 of the rect of fld test - item
2 of the rect of fld test) into fldHeight
    -- gives the height of the field in pixels
put fldHeight / the textHeight of fld test into numLines
    -- gives the number of displayed lines
    -- NOTE! this does not account for carriage returns in the field
put "the number of lines is" && numLines

set the style of fld test to holdStyle
set the rect of fld test to holdRect
unlock screen
end mouseUp
```

This article last reviewed: 30 May 1989

Farallon, in its PhoneNET connector documentation, recommends that users not connect a LocalTalk connector directly to a twisted-pair backbone via a PhoneNET to LocalTalk adapter cable. The reason is that LocalTalk connectors don't have sufficient surge protection when connected directly to the phone line. The documentation says that the first connector out of the wall should be a PhoneNET connector. Then, it's safe to branch LocalTalk from that using the adapter cable.

Farallon incorporates a proprietary transformer and surge protection system into their connector modules. They do this because phone wire is not shielded and is subjected to RFI and EMI. Because LocalTalk cable is shielded, the same level of surge protection is not required in LocalTalk connectors. Connecting LocalTalk cable to PhoneNET via an adapter is not recommended, because it reduces the shielding effect at the cable. There are other reasons, including differences in impedance. Farallon's suggestion correctly interfaces phone wire to LocalTalk with a module that provides some form of surge suppression.

Y-Term FTP: Converter Available for the Macintosh

=====

This article last reviewed: 26 May 1989

Y-term is a file transfer protocol used on some IBM mainframe computer systems. FutureSoft sells a program, called DynaComm, that provides the Y-term file transfer protocol for the Macintosh. The communication session must be initiated through an IBM 7171 or Series 1 protocol converter. The terminal that is emulated is a VT100.

For more details, search the Tech Info Library under "FutureSoft."

A/UX: Output Is Lost in "term" and X11

=====

Article Created: 21 August 1989

Article Change History

-----

08/31/92 - REVIEWED

•For technical accuracy

TOPIC -----

The following problem indicates a bug in A/UX. The following small program produces a list of 10,000 lines when run:

```
#include <stdio.h>

main()
{
    int i;

    for (i=1; i<10000; i++) {
        printf ("i=%d\n",i);
    }
}
```

This works as expected when running on the console or as single process in "term". However, when this program is started three times in different windows of "term", the output is garbled. When tested under X11, the output is also garbled.

Tech Comm has verified this problem on both the Toolbox application "term" program and the X Window System "xterm" program. Some of the standard output of the program from the last window(s) are lost, if more than two windows (either created by "term" or "xterm") run the test program.

The problem can be reproduced and easily seen by outputting a longer string, like "i====", through the printf() statement.

It seems that both "term" and "xterm" window programs have some limitation on the synchronization of each terminal emulation output. They just do the normal asynchronous terminal output.

However, you may use the "tee" pipe-fitting command to block the standard output on the display without losing any output. For example:

```
foo | tee [file]
```

This lets the output of the program "foo" be displayed on the standard output and/or copied to the file, if the optional file is specified.

DISCUSSION -----

The problem described in this article has been submitted as a bug to A/UX Engineering.

## MPW: PixMap Color Issue

Revised: 8/21/89  
Security: Everyone

MPW: PixMap Color Issue

=====

This article last reviewed: 9 June 1989

A programmer has a PixMap with a Raster image that has 8-bit pixel values ranging from 0 to 127 and is using CopyBits with the SrcCopy mode. The foreground and background colors are correctly set. The color window has 128 animating colors reserved.

The question is what color table should be assigned to the PixMap? Does he need to use the color table generated by the PaleteToCTab call with the source palette being the palette of the color window?

A NIL handle results in a black and white image. (Note: With tolerant colors used instead of animating colors, the picture appears OK, but you can't animate the colors.)

You can create a similar problem without involving a PixMap. When you use animating entries in the palette, you always get a black and white picture. When you use tolerant entries, we get color. This is a similar problem.

A solution is to use calls to AnimateEntry as a replacement for SetEntryColor. When you use SetEntryColor with animating color entries, you always get black and white. When you use AnimateEntry to set an entry's color, you get color. Specifically:

```
SetPalette(mywindow, mypalette, false);
mycolor.red := 65535;
mycolor.green := 0;
mycolor.blue := 0;
AnimateEntry(mywindow, 2, mycolor);
ActivatePalette(mywindow);
PMForeColor(2);
PaintRect(myrect);
```

yields a red rectangle. If you replace the AnimateEntry call with a

SetEntryColor call, you get a black rectangle. The code segment above assumes "mywindow" is a window pointer to a color window. "mycolor" is a variable of type rgbcolor. "mypalette" is a variable of type palettehandle. "myrect" is a variable of type rect.

## HyperCard: Method To Check Presence of XCMD

Revised: 6/24/90  
Security: Everyone

HyperCard: Method To Check Presence of XCMD

=====

This article last reviewed: 9 June 1989

Programmers have asked if HyperCard, has a way to check if an XCMD is installed in a stack? For example, you create a button that requires a certain XCMD to function. You distribute the button to other HyperCard users, but you don't know if they have the particular XCMD installed in their Home Card.

The fact is that HyperCard has no way to determine if a particular XCMD is present. However, it would be a simple matter to write an XFCN that would check for the presence of specific XCMDs and XFCNs. This XFCN would need to use Resource Manager calls, like GetNamedResource and ResError, to see if the XCMD was currently available.

## ImageWriter II: Condensed Printing from Macintosh (11/94)

Revised: 11/14/94  
Security: Everyone

ImageWriter II: Condensed Printing from Macintosh (11/94)

=====

Article Created: 21 August 1989  
Article Reviewed/Updated: 14 November 1994

TOPIC -----

This article describes printing in a condensed mode on the ImageWriter II.

DISCUSSION -----

If you want an ImageWriter II to print in a condensed font, you can define that through the DIP switches. However, when you are printing using the ImageWriter II driver from a Macintosh, the configuration is overridden by the driver software.

The Macintosh might support condensed print when draft mode printing is selected in the Print dialog box. However, the application doing the printing must support condensed printing. The reason is that the print drivers, by default, override the switch settings and turn off the condensed mode.

To have all applications print in condensed mode, you would have to patch the print drivers at the point where they actually override the switch settings of the ImageWriter II. This is unsupported and undocumented.

The best solution is to utilize a font which is condensed in nature.

## AppleShare 2.0.1: Multi-Launching Problem (2/95)

Revised: 2/10/95  
Security: Everyone

AppleShare 2.0.1: Multi-Launching Problem (2/95)

Article Created: 9 June 1989  
Article Reviewed/Updated: 10 February 1995

TOPIC -----

I was able to multi-launch these applications on an AppleShare 1.1 server:

MacDraw 1.9.6  
MacDraw II  
MacWrite 5.0  
MacPaint 2.0  
PageMaker 3.0.

After I upgraded the server to AppleShare 2.0.1, they don't multi-launch anymore, why not?

DISCUSSION -----

We were able to multi-launch MacPaint 2.0, MacWrite 5.0, and MacDraw II using AppleShare 2.0.1. (We did not try the other applications.) These are the steps taken to get the Finder to allow the applications to launch multiple times:

### Step 1

Copy the applications to a folder on an AppleShare 2.0.1 server.

### Step 2

Using ResEdit 1.2b3, or later, turn on the shared bit of each application.

This is a point to double check. In at least two of the cases, a later check show the Shared bit was still not set; the operation did not take.) After you set the bit, quit ResEdit, relaunch ResEdit, and ensure that the bit stayed set.

### Step 3

Make the folder containing the application a read-only folder. When the folder was not read-only, only MacDraw II would multi-launch; the other applications

would not.

The flipping of the bundle bit should have no effect on whether an application will multi-launch. However, older versions of ResEdit did accidentally switch the shared and bundle bits, which may have been causing this problem. Make sure to use ResEdit 1.2b3 or later. We have verified that this version works.

IMPORTANT: Setting these bits is dangerous; these applications are not supported as multi-launch applications. The effects of multi-launching are unknown. Also, keep in mind possible licensing problems, because those applications are sold as single-user applications.

## Apple IIGS: Known ImageWriter LQ and Bin Selection Problem

Revised: 8/21/89  
Security: Everyone

Apple IIGS: Known ImageWriter LQ and Bin Selection Problem

=====

This article last reviewed: 9 June 1989

Some LocalTalk users are unable to select paper bins on the cut-sheet feeder with the Chooser. These users get a "paper out" error message when using the LocalTalk ImageWriter LQ with an Apple IIGS. Yet, when the ImageWriter LQ is directly connected to the Apple IIGS, bin selection works fine. A typical system giving rise to this problem includes:

- an Apple IIGS with LocalTalk PC Card
- a LocalTalk ImageWriter LQ
- a cut-sheet Feeder

The problem appears to be with the LocalTalk interface for the ImageWriter LQ. The escape codes required for changing the bins get stripped from the packets sent to the ImageWriter. At this time, there is no known workaround for this problem.

## WordStar and LaserWriter: Page Dimension Problems

Revised: 3/4/90  
Security: Everyone

WordStar and LaserWriter: Page Dimension Problems

=====

This article last reviewed: 9 June 1989

A user has an IBM PC with LocalTalk PC Card and is running WordStar Professional 4.0. He wants to emulate an Epson printer using the LaserWriter program, without having to modify existing documents. He has run up against four problems:

- page width differences
- page length differences
- inability to print overstrikes
- lack of a ".sr" dot command

He prints through the LaserWriter program, using the WordStar option. The results are not good. Text is cropped about 3/8 inch from the right edge of page. Thus, many lines lose a few characters on right.

Second, the LaserWriter prints fewer lines per page than a dot-matrix printer (like an Epson) does. Thus, for each logical page printed, he gets one printed page full of text and a second page either blank or with a single line of text at the top of the page.

The improper cropping of text 3/8 inch from the right edge of the page (causing some characters to be "lost" off of the side of the page) may be caused by margin settings. More than likely, it is caused by switching font sizes within the document.

For example, if a 10-point Courier is chosen and Bold text is selected, the larger bold text may run off the side of the page. This is because the LaserWriter utility assumes that the 10-point Courier size is the size of ALL text within the document and will not take into account a larger text size, whether from bolding or simply using a different font size within the document.

If a line of text is typed, but due to the size of the actual printed text, it will not fit on the printed line, the rest of the characters

will be cut as they print off of the right side of the page. The LaserWriter utility will position the text on the line and attempt to print it on the line in which the text appeared, regardless of whether or not the text actually fits on the line when scaled to the user's selected size. The only recourse is to limit the number of characters for those lines where the problem appears or, if the entire document is affected, to print with smaller text sizes.

Text cropped off of the bottom of the page is due to the same reasons as cropping lines.

The LaserWriter program does not implement the WordStar "overstrike" command. This command, basically, puts a backspace in the text. Neither is the ".sr" dot command present.

## WordStar and LaserWriter: Character Set Problems

Revised: 3/4/90  
Security: Everyone

WordStar and LaserWriter: Character Set Problems

=====

This article last reviewed: 9 June 1989

A user has an IBM PC with LocalTalk PC Card and is running WordStar Professional 4.0. He wants to emulate an Epson printer using the LaserWriter program, without having to modify existing documents. His question concerns how the international character sets 1 and 2 produce diphthongs (for example, the ae character).

Diphthongs, like AE or OE, are part of the standard LaserWriter character set (see page 255 of the PostScript Language Reference Manual from Adobe Systems Incorporated, published by Addison-Wesley, ISBN 0-201-10174). The standard LaserWriter character set and the unencoded character set can be mapped to a single font (see pages 254 and 255 of the "PostScript Language Reference Manual"). The symbol set (pages 256 and 257) cannot be mapped together with the standard LaserWriter character set or the unencoded character set into a single font.

Here are three questions with answers concerning diphthongs and fonts:

1) Does the Courier font include diphthongs?

Diphthongs are part of the standard LaserWriter character set and are included in the Courier font. Using the standard character set, the diphthongs (AE, OE, ae, and oe) are ASCII codes 225, 234, 241, and 250, respectively.

These characters are mapped to new positions using extended international character sets 1 and 2. Selecting either international character set 1 or 2 from the LaserWriter print options for WordStar documents will allow access to the AE and ae diphthongs at ASCII locations 146 and 145, respectively. See page 91, "Printing from extended character sets" in Appendix A. The OE and oe characters are in the same locations and can be accessed with the same codes as in the standard character set.

2) If the answer to number 1 is no, from which character set do the diphthongs come if one is printing in Courier with international 1 extended characters?

As stated in the answer to question 1, diphthongs are available through the Courier font.

3) If the answer to number 2 is a proportionally spaced font, like Helvetica or Times, how does the use of diphthongs from proportionally-spaced fonts from another font fit with your reasoning that symbol font characters cannot be remapped in this manner, because they are from another font and are proportionally spaced?

Neither Helvetica nor Times fonts, containing standard or unencoded characters, can be mapped with Symbol set characters due to the limitation restated in the question. This is because the Adobe PostScript command, which is used to merge character sets into a single font definition, is limited to the Standard LaserWriter and unencoded character sets.

Symbol set characters cannot be used with proportionally spaced fonts even though both use proportionally spaced graphic images because there is only one set of commands used for merging character sets into a font.

The limitation is not in the use of the commands (as in the hypothetical case of mapping proportional characters with proportional symbols), but in Adobe's limiting implementation of their commands. This causes the remapping not to work with Symbol set characters and standard LaserWriter and unencoded character sets. This means that standard characters and unencoded characters are accessible within Helvetica and Times. Symbol set characters remain inaccessible from the same remapped font. Note: Character sets are not fonts. Fonts are the graphical images to which the character sets are mapped.

## MC68030: The Meaning of Internal Harvard Architecture

Revised: 9/28/92  
Security: Everyone

MC68030: The Meaning of "Internal Harvard Architecture"

=====

Article Created: 9 June 1989

### Article Change History

-----

09/28/92 - REVIEWED

- For technical accuracy.

### TOPIC -----

What does "Internal Harvard Architecture" mean?

### DISCUSSION -----

The phrase "Internal Harvard Architecture" has been applied to the Macintosh IIcx. "Harvard Architecture" refers to section 1.8 of the MC68030 User's Manual, Pipelined Architecture. The manual states:

"The MC68030 uses a three-stage pipelined internal architecture to provide for optimum instruction throughput. The pipeline allows as many as three words of a single instruction or three consecutive instructions to be decoded concurrently."

This is a 68030 chip design element that allows faster throughput of the microprocessor's instructions. It is not specific to the Macintosh IIcx; it also is valid for the Macintosh IIX and the Macintosh SE/30.

Apple IIGS: Memory Requirements for AppleShare Networking

=====

This article last reviewed: 9 June 1989

The Apple IIGS requires 768K of memory to load all of the resources needed for network operation and all of the operating system and to still have room for applications. However, some users have reported running successfully with just 512K of RAM.

If you're running with 512K of RAM, and no problems have surfaced, you have been extremely lucky in the use of your networked Apple IIGS systems. The 512K configuration is not a supported environment for networked Apple IIGS systems. Should difficulties occur in the future, immediately increase RAM to 768K.

## 3278 Terminal Emulation Over TCP/IP (9/95)

Revised: 9/28/95  
Security: Everyone

3278 Terminal Emulation Over TCP/IP (9/95)

=====

Article Created: 14 June 1989  
Article Reviewed/Updated: 28 September 1995

TOPIC -----

A Government contractor needs a 3278 terminal emulator. The emulator must work over a TCP/IP hardware connection, in the same way that asynchronous terminals are emulated by NCSA Telnet.

DISCUSSION -----

There are three third-party vendors that we know of which provide what you are looking for. Here is what we know about them.

Attachmate's EXTRA! for Macintosh 2.0 is a TN3270 emulator that lets Macintosh users connect to mainframes over NetWare for SAA as well as over TCP/IP, FTP file transfer to IBM hosts. Also a new 3278 host-printer emulation lets you preview, format, and print terminal documents to AppleTalk printers.

5 PM TermOffice 3.0 from About Software provide a wide range of terminal emulations, including those for IBM mainframes; AS/400 midrange computers, and VAX, UNIX, Unisys, and Honeywell/Bull hosts.

The following information was taken from an AppleLink article in the "News" section of the "Third-Party Press Releases" folder. The article is called "Update to TCP/Connect: IBM TN3270 Terminal Emulation".

InterCon's TCP/Connect gives users access to the power of the Department of Defense networking standard TCP/IP. TCP/IP was developed so that computers of different types could communicate over a mixed-media network. TCP/IP offers a standard way to transfer files, emulate terminals, and other functions between dissimilar computers and operating systems.

Apple has announced support for TCP/IP with the introduction of MacTCP (a set of TCP/IP drivers for the Macintosh). InterCon supports MacTCP. IBM 3278 emulation is included in the TCP/Connect-Extended and in the TCP/Connect-3270 software

packages. TCP/Connect features include Telnet, FTP, and varied hardware support:

#### Telnet

-----

Telnet is an implementation of the standard, virtual-terminal protocol through which you log onto any Telnet-supporting host. Features included in TCP/Connect are:

- Tektronix(TM) 4014 emulation
- IBM 3278 emulation through TN3270 Protocol
- DEC VT102 emulation
- DEC VT240/241 graphics terminal emulation
- Copy of graphics from any of the graphics terminals
- Copy/Paste of text between sessions and other applications
- Up to 20 simultaneous sessions
- Scroll-back within the terminal window
- User-defined macro keys

#### FTP

---

FTP, the File Transfer Protocol, lets you transfer files to and from remote hosts using a Macintosh. The remote host must have an FTP server in operation. ASCII, binary, and MacBinary transfers are supported.

#### Supported Hardware

-----

Hardware supported by TCP/Connect include:

- Macintosh Plus, SE, SE/30, II, IIX, and IICx
- Kinetics EtherSC(TM), EtherSE(TM), and EtherPort II
- Dove FastNet II(TM), FastNet III(TM), Marathon LAN 020
- 3Com EtherLink II(TM), EtherLink/SE
- Everex
- Apple EtherTalk any EtherTalk compatible device

Including any LocalTalk to Ethernet gateways, like the GatorBox by Cayman Systems, and Kinetics FastPath devices.

The Tech Info Library article titled "Locating Vendor Information" can help you search for a particular vendor's address and phone number.

## AppleShare Print Server: Out-of-Paper Message

Revised: 8/21/89  
Security: Everyone

AppleShare Print Server: Out-of-Paper Message

=====

This article last reviewed: 14 June 1989

TOPIC -----

This is regarding the AppleShare Print Server. On page 53 of the Print Server's Admin Guide, it states that "If a printer is out of paper, or if the paper is jammed, a message appears not only in the status line of the print queue window but also on the screen of every workstation that's spooling a document to the print server."

We could not get a message or a beep from any of our workstations. The server was the only device that indicated that the printer was out of paper. Is the manual wrong? Could you clarify the situation for us?

DISCUSSION -----

The "AppleShare Print Server User's Guide" states that error messages appear on the screens of all workstations that are spooling documents. Once the spooling process is complete, no messages are sent to the user. The print server starts making the connection to the printer as soon as it starts receiving data packets.

In many cases (especially those involving short documents, busy networks, or large networks), it is possible for the entire document to be spooled before the connection to the printer is established. This eliminates the reporting of any printer errors to the user. Once the server is aware of a problem with a spooled printer, all users who try to spool are notified of the problem when they try to print.

## Macintosh SE/30: Recommended Way To Connect Kodak DataShow

Revised: 9/28/92  
Security: Everyone

Macintosh SE/30: Recommended Way To Connect Kodak DataShow

=====

Article Created: 15 June 1989

### Article Change History

-----

09/28/92 - REVIEWED

- For technical accuracy.

### TOPIC -----

Connecting the Kodak DataShow to the Macintosh SE/30 created quite a controversy as to which chip and pin on the logic board contains the signal for the pixel clock.

### DISCUSSION -----

Initially, an article stated that pin 1 of UG6 was the correct location to find the pixel clock (according to the engineer who designed the logic board). Soon thereafter, Kodak recommended pin 1 of UG7.

A copy of the Macintosh SE/30 logic board schematics showed that both pin 1 of UG6 and pin 1 of UG7 are tied together and generate the same signal. In fact, several chips on the logic board, beside UG6 and UG7, generate the pixel clock signal. Engineers confirmed this with a continuity meter and verified a connection between pin 1 of UG6 and pin 1 of UG7. An oscilloscope also verified that the signals were identical.

Tech Comm engineers obtained a Kodak DataShow unit and successfully installed it on pin 1 of UG6 and pin 1 of UG7. Perhaps other factors caused the unsuccessful installations of the DataShow unit on UG6 and UG7. For example, perhaps pin 1 and pin 2 were shorted together. It is also possible that a good connection was not made between pin 1 and the DataShow interface.

Recommendation: Use pin 1 of UG7. This is for two reasons:

- 1) Pin 1 of UG7 is what Kodak recommends.
- 2) It is easier to install the DataShow connector on pin 1 of UG7.

## A/UX: Bourne Shell Resource Loophole

Revised: 9/18/92  
Security: Everyone

A/UX: Bourne Shell Resource Loophole

=====

Article Created: 15 June 1989

### Article Change History

-----

08/31/92 - REVIEWED  
• For technical accuracy.

### TOPIC -----

The Bourne Shell has had a well-known and famous resource loophole since version 7. This article describes it.

### DISCUSSION -----

The following line of code starts a big loop that exhausts memory after a while.

```
$<<`ls`
```

This yields messages like "Swap space running out, Needed xx pages", and you have to "kill" the program. The "kill" generates a core file that is LARGE. In most cases, the core file can't be dumped on the file system, due to lack of space.

## Macintosh-to-AT&T 3B2 Cable Pinout (9/94)

Revised: 9/14/94  
Security: Everyone

Macintosh-to-AT&T 3B2 Cable Pinout (9/94)

Article Created: 15 June 1989  
Article Reviewed/Updated: 13 September 1994

TOPIC -----

A company needs a cable to connect a Macintosh SE, Macintosh II, Macintosh IIX, or Macintosh IICx to its AT&T 3B2. They want to go directly from the Macintosh (mini DIN-8) to an RJ45 female on the 3B2. This is not a dial-in situation. The 3B2 will be in close proximity to the Macintoshes.

DISCUSSION -----

Currently, AT&T terminals direct-connect asynchronously through twisted-pair cabling with RJ45 plugs on each end. On the terminal side, the RJ45 plugs into a hardware flow control plug that snaps onto the back of the terminal. On the 3B2 side, the RJ45 plugs directly into one of the ports on the back of the 3B2. AT&T indicates that the pin configurations on the 3B2 are:

| Pin # | Transmission Type |
|-------|-------------------|
| 1     | SG lead           |
| 2     | CTS (?) lead      |
| 3     | TxD lead          |
| 4     | DTR lead          |
| 5     | RXD lead          |
| 6     | DCD lead          |
| 7     | PG lead           |
| 8     | RTS (?) lead      |

The Macintosh Mini DIN-8 port pins have the following correspondent functions required to use them for RS-232:

Mini DIN-8

| Pin# | Function               | RS-232 | Pin# |
|------|------------------------|--------|------|
| 1    | HSKo (Handshake input) | DTR    | 20   |

|   |                                                |     |   |
|---|------------------------------------------------|-----|---|
| 2 | HSKi (Handshake output)                        | DCD | 8 |
| 3 | TxD- (Transmit data, negative going component) | TXD | 3 |
| 4 | GND (Chassis/Signal ground)                    | GND | 7 |
| 5 | RxD- (Receive data, negative going component)  | RXD | 2 |
| 6 | TxD+ (Transmit data, positive going component) | GND | 7 |
| 7 | GPI (General-Purpose input)                    | NC  |   |
| 8 | RxD+ (Receive data, positive going component)  | GND | 7 |

According to AT&T 3B2 pin configurations with RJ45 plugs described above, you can make a cable with the following pinouts and signals for the direct connection between an AT&T 3B2 and a Macintosh SE, Macintosh II, Macintosh IIX, or Macintosh IICx:

|                 | Macintosh  |         | AT&T 3B2      |                 |
|-----------------|------------|---------|---------------|-----------------|
|                 | Mini DIN-8 |         | RJ45          |                 |
| Signal (in/out) | Pin#       |         | Pin#          | Signal (in/out) |
| -----           | -----      |         | -----         | -----           |
| HSKo (out)      | 1          | <-----> | 4             | DTR lead (in)   |
| HSKi (in)       | 2          | <-----> | 2             | CTS lead (out)  |
| TxD- (in)       | 3          | <-----> | 3             | TxD lead (out)  |
| GND             | *4         | <-----> | 1             | SG lead         |
| RxD- (out)      | 5          | <-----> | 5             | RXD lead (in)   |
| TxD+            | *6         | <-----> |               |                 |
| GPI             | 7          | <-----> | No Connection |                 |
| RxD+            | *8         | <-----> |               |                 |

\*There are many variations for connecting pins 4, 6, and 8, but the basic intent is to bring all three of these pins to ground on the Macintosh side. Connect Signal Ground to Chassis Ground if you want a slightly better noise margin.

If the above configuration doesn't work, try the following cable connection:

|            |   |   |               |
|------------|---|---|---------------|
| HSKo (out) | 1 | 8 | RTS lead (in) |
|------------|---|---|---------------|

Currently, Tech Comm does not know of an Apple cable product that has been made for this particular configuration (Circular Mini DIN-8 <-> RJ45 plug).

However, if the standard RS-232 DB-25 connectors are directly used in AT&T 3B2, the Apple cable finished product number A2C0311, same as Part Number 590-0331 (beige color), or A2C0312, same as Part Number 590-0555 (smoke color), a circular Mini DIN-8-to-DB-25 cable, can be used for the connection between the 3B2 and the Macintosh.

Because the AT&T 3B2 is a UNIX-based system, any Macintosh under Macintosh OS can be connected via:

- 1) A direct serial line or a modem, and use MacTerminal as a VT100 terminal emulator to access the AT&T 3B2.
- 2) An Ethernet with EtherTalk card (for Macintosh II, Macintosh IIX, or Macintosh IICx) or EtherPort SE card (for Macintosh SE), and use NCSA Telnet or MacTCP software to connect to the 3B2 machine. Of course, the

3B2 must have Ethernet TCP/IP capability.

A Macintosh II, Macintosh IIX, or Macintosh IICx, running A/UX, also can be connected to a 3B2 machine via:

- 1) A direct serial line or a modem by using any UNIX communication software program, such as "cu", "tip", "uucp", or "kermit", to connect to the remote 3B2 machine.
- 2) An Ethernet with EtherTalk card (for Macintosh II, Macintosh IIX, or Macintosh IICx) by using Internet protocols software, like "telnet", "rlogin", or "ftp". Of course, the 3B2 machine needs to have Ethernet TCP/IP capability.

## HD80 SC and HD160 SC Drives: Noise Levels

Revised: 9/29/90  
Security: Everyone

HD80 SC and HD160 SC Drives: Noise Levels

=====

This article last reviewed: 22 June 1989

TOPIC -----

This article gives the noise levels for the HD80 SC and HD160 SC drives.

DISCUSSION -----

The noise specifications for all of Apple 3.5-inch hard drives are the same. Measurements are taken 1 foot from the drive. At idle, the noise level is to be no greater than 45 dba. At seek, the noise level is to be no greater than 50 dba.

Status of Switcher

=====

This article last reviewed: 22 June 1989

TOPIC -----

This article discusses the status of Switcher as of June 1989.

DISCUSSION -----

- 1) Switcher was not a public domain product and has been discontinued.
- 2) It still is supported by Apple: Finder 5.3, System 3.2.
- 3) For most users, Switcher has been replaced by MultiFinder. However, it is still a viable option for Macintosh XL, Macintosh 512K, Macintosh 512Ke, and 1MB Macintosh Plus systems.

## Altos Files: How to Transfer them to/from a Macintosh

Revised: 8/21/89  
Security: Everyone

Altos Files: How to Transfer them to/from a Macintosh

=====

This article last reviewed: 22 June 1989

TOPIC -----

A customer wants to transfer (word processing) files from an Altos, running Altos Office Management System, to a Macintosh for page composition.

DISCUSSION -----

The Altos Office Management System runs under the Xenix operating system, Microsoft's variation on UNIX. Xenix and UNIX store all data and applications in the same type of file. This file type may contain any ASCII value from 0 to 255. If the word processor can save a plain ASCII text file, Macintosh can accept the file with little work. However, if the word processor only creates files that also contain Control, Escape, or extended characters, these additional characters need to be removed before Macintosh can make use of the data in the file.

If the file does contain Control, Escape, or extended characters, a filter or translation program is needed to extract the plain text characters stored in the file. This can be accomplished on the Altos side or the Macintosh side. On the Xenix side, "sed" (the stream editor) can be used to change or eliminate unwanted characters. Also, on Xenix, the "strings" command can be used to extract only printable ASCII characters from a file. On the Macintosh side, utilities, like Vantage (McSink), can strip unwanted control characters from the file.

Moving either of these files to the Macintosh is relatively simple. Using a serial connection (direct serial port-to-serial port or two modems), the file can be moved with a standard file transfer protocol, like Kermit. You can also have Xenix "stream" or "print" the file to a serial port. If the Macintosh is set up to capture the data coming from the Altos serial port, the captured data can then be copied and pasted from the capture buffer. A capture buffer is provided in MacTerminal by selecting the Record Lines Off Top under the Commands menu.

Macintosh: B-Tree Indexing Software

=====

This article last reviewed: 22 June 1989

TOPIC -----

Does Apple have anything comparable to B-trieve from Softcraft (sold by Novell)? Apparently, it gives C programmers access to retrieval functions for Novell file services?

DISCUSSION -----

B-trieve is a B-tree indexing system for MS-DOS. Softcraft-Novell are planning to develop B-trieve for the Macintosh. When a Macintosh version is completed, both Macintosh and MS-DOS applications using B-trieve will be able to access the same files.

There are B-tree indexing products available for Macintosh. These are not specific to a Novell environment and will not work with Softcraft's B-trieve product.

- db\_VISTA v. 3.0 is a database development environment using B-tree indexing in the C language from Raima Corp.
- C-Data Manager has B-Tree indexing with multiple keys from Database Technologies
- C-Tree File Handler provides low-level B+Tree utilities from Faircom
- Turbo Pascal Database Toolbox uses B-tree indexing methods from Borland International

For more details, search the Tech Info Library under "Raima", "Database Technologies", "Faircom", and "Borland".

## AppleShare: Apple II Practical Node Limits

Revised: 3/27/90  
Security: Everyone

AppleShare: Apple II Practical Node Limits

=====

This article last reviewed: 28 February 1990

TOPIC -----

How many Apple IIs can be started up from an Macintosh SE/30 AppleShare File Server? Theoretically, 50 nodes can be logged on to an AppleShare file server at a time, but what is the practical limit? I've never seen an Apple II network larger than about 30 nodes, so I can't really estimate the degradation in performance. Do you know of any sites running 40 or more Apple IIe or Apple IIGS systems off of one file server?

DISCUSSION -----

With 1MB RAM, a Macintosh SE/30 allows 25 Apple II workstations to start up from the server at the same time. With 2MB RAM, the limit is increased to 50 Apple II workstations.

The practical limit for booting depends on the user's situation. For example, 20 Apple IIGS systems starting up at same time from the same server takes approximately 10 minutes, whereas 20 Apple IIe systems take about 4 minutes. The reason is that the Apple IIGS has more than 120K to load across the network, compared to about 20K for the Apple IIe.

The practical limit for workstations logged on to one server depends on the amount of activity taking place on the network. With low traffic, 50 users logged on at one time may be acceptable. As traffic becomes heavier, it is probable that the practical maximum number of active users will decrease.

## AppleColor Monitor: Chrominance and Luminance Specifications

Revised: 8/21/89  
Security: Everyone

AppleColor Monitor: Chrominance and Luminance Specifications

=====

This article last reviewed: 22 June 1989

TOPIC -----

A customer has requested the following specifications for the AppleColor Monitor:

CIE Chromaticity Coordinates

Phosphor Types

White Point Specifications:

Typical or normal luminance level in footlamberts

Color temperature

Contrast ratio

Center-to-corner uniformity as a percentage of center level

DISCUSSION -----

Due to contractual agreements, the only specification available for release is the typical luminance level.

The AppleColor High-Resolution RGB Monitor (M0401) has a luminance level of 20 footlamberts with the brightness control in the center detent position. With the brightness control in the full-open position, the luminance level is 25 footlamberts.

## Apple HD Backup 1.1: 800K InvisHDMMainBo3b Invisible File

Revised: 8/21/89  
Security: Everyone

Apple HD Backup 1.1: 800K "InvisHDMMainBo3b" Invisible File

=====

This article last reviewed: 22 June 1989

TOPIC -----

Why does HD Backup version 1.1 create an 800K invisible file called "InvisHDMMainBo3b". Do you have any idea why it should be so large?

DISCUSSION -----

The "InvisHDMMainBo3b" invisible file contains only 4 bytes of data and should be no larger than 2K. The file stores the date of the last backup.

Neither Tech Comm nor the programmer of HD Backup knows why the file would grow to 800K. If anyone in the field has experienced this problem and knows the cause, please AppleLink TECH.COMM.

Macintosh SE/30: Third-Party Color Card Availability

=====

Article Created: 22 June 1989

### Article Change History

-----

09/28/92 - REVISED

- To include information on Micron Technologies.

02/09/93 - UPDATED

- Micron Technologies acquired by Xceed Technologies.

### TOPIC -----

I'm looking for a color card for the processor-direct slot in the Macintosh SE/30 that supports the AppleColor High-Resolution 13-inch RGB Monitor. Do you know of any?

### DISCUSSION -----

SuperMac Technologies, and RasterOps make cards for the processor-direct slot in the Macintosh SE/30 that supports the AppleColor High-Resolution 13-inch RGB Monitor.

The SuperMac Spectrum Series II for the Macintosh SE/30 supports standard display resolutions of 640 x 480, 640 x 870, and 1024 x 768. The board supports 256 colors or grayscales at these resolutions. Monitors supported include the Apple High-Resolution 12-inch Monochrome Monitor, the AppleColor High-Resolution 13-inch RGB Monitor, the Apple Macintosh Portrait Display, and various SuperMac monitors.

The RasterOps Colorboard 108 SE/30 for the Macintosh SE/30 supports standard display resolutions of 640 x 480, 800 x 600, and 1024 x 768. The board supports 256 colors or grayscales at these resolutions. Monitors supported include the Apple High-Resolution 12-inch Monochrome Monitor, the AppleColor High-Resolution 13-inch RGB Monitor, and various RasterOps monitors.

In addition, Micron Technologies (acquired by Xceed Technolgoies) also makes both 8-bit and 24-bit color video cards for the SE/30.

## Macintosh: Menu Bar Emulation for Multiple Monitor System

Revised: 8/21/89  
Security: Everyone

Macintosh: Menu Bar Emulation for Multiple Monitor System

=====

This article last reviewed: 20 July 1989

TOPIC -----

Can you create a Macintosh application that puts the menu bar on all of the monitors of a multiple monitor workstation, or does that break an "Inside Macintosh" rule? If you can, what is the maximum number of monitors?

DISCUSSION -----

The Macintosh Toolbox does not provide a method for placing actual menu bars on multiple monitors. Only one monitor can have the menu bar.

It is possible to write an application that creates pop-up menus at the top of each monitor that emulate the menu bar while that application is running. Information on pop-up menus is on pages 241 and 242 of "Inside Macintosh Volume V" and "Tech Note #156."

An easy solution would be a third-party product, like POWERmenus from Magic Software. With it, you can display a hierarchical pop-up menu containing the same items as the real menu bar anywhere on any screen. This utility works with all applications.

There is another INIT utility called "Tear-Off Menus" (TOM) from AIP (Advanced Interface Programming). With TOM, a user can tear off either "pull-down" menus or the titles of the menus, which then can be activated in the same manner as standard menus. Menus also can be dragged across multiple monitors. You can also set TOM to automatically disable with applications that "misbehave". Some of these applications are specified (hard-coded). You can expand the list to include other applications that don't work correctly.

The product incorporates a serialization scheme for counting users on the network. So, if, for example, you want to have five people running TOM on one network, you need to buy a "large" enough license to support that number.

For more details, search the Tech Info Library under "Magic Software" and  
"Advanced Interface Programming."

## LaserWriter Family: How the Out of Paper Notification Works

Revised: 8/21/89  
Security: Everyone

LaserWriter Family: How the Out of Paper Notification Works

=====

This article last reviewed: 22 June 1989

TOPIC -----

A customer has asked why the Macintosh no longer beeps when the selected LaserWriter is out of paper as it did with previous versions of printer drivers and PrintMonitor.

DISCUSSION -----

The LaserWriter family of printers, in conjunction with Apple's printer drivers, still reports to the user when the LaserWriter is out of paper, if it is printing more than a single page.

The LaserWriter will image one page with a paper-out condition and not report the error to the user. For example, the LaserWriter is out of paper and no image is in the LaserWriters memory. A one-page print job is sent to the LaserWriter. The page is imaged, and no error is sent to the machine that sent the print job.

If a page has been imaged and another page or more than one page is sent to a LaserWriter with no paper, the machine that sent the print job will be notified that a paper-out condition has occurred.

## CD-ROM: Some Tips on How to Create One

Revised: 7/27/93  
Security: Everyone

CD-ROM: Some Tips on How to Create One

Article Created: 21 June 1989  
Article Reviewed/Updated: 12 July 1993

TOPIC -----

This article discusses the process for preparing data for a CD-ROM pressing. It assumes that you're looking at a moderate number of CDs (100 to 1000).

For more detailed information refer to the "Apple CD-ROM Handbook" published by Addison-Wesley, ISBN 0-201-63230-6. The handbook is a guide to planning, creating, and producing a CD-ROM.

DISCUSSION -----

It makes sense to press a CD-ROM if you have 10 megabytes or more of data and need 100 or more copies of it. CD-ROMs behave just like a locked, fast, very big floppy. If you can run your program or Hypercard stack on a locked floppy, it will run on a CD-ROM.

To press a CD-ROM, you have two options: the easy way and the way with many sophisticated options. The easy way gives you a Macintosh CD that's a copy of a hard disk. The second way gives you the Macintosh CD plus the ability to create CD-quality sound tracks. You can also create a CD in High Sierra format. High Sierra discs can be used across many operating systems.

The easy way is to put all of your data onto an ordinary Apple hard disk and send it to one of the companies listed below. They will create an image copy (an exact duplicate) of your hard disk and put that image onto CDs.

The basic costs for such a CD include a mastering charge (for creating the initial image) plus a duplication charge for each CD. The mastering charge varies (depending on how quickly you want it done), but usually starts under \$1000. The duplication charge is around \$1 to \$2.00 per CD. The average turn-around time is 5 to 10 days.

If you want faster turn-around time, you must pay additional money. Typical mastering charges for one-day turnaround start above \$2500. If you want large numbers of CDs, you'll pay less money.

Some disc-pressing companies: (See the "Apple CD-ROM Handbook" for a more complete listing of companies.)

- 3M Optical Recording
- Digital Audio Disc Corporation (DADC)
- Discovery Systems
- Philips Dupont Optical

The sophisticated way of pressing a CD-ROM demands a pre-mastering system to create a tape. The pressing plant uses this tape, rather than a disk, to create the master. Tape provides greater flexibility, because you control what goes on the tape. You need much more technical knowledge. You also need access to a pre-mastering facility. A typical fee for pre-mastering is \$250 to \$500, depending on the number of files on the disc.

There are companies that rent time on their pre-mastering system and help you with the details (for a fee). One of these is Optical Media International. Other companies will probably appear as the market matures.

If you want to press a CD that can be used on different operating systems, use the High Sierra volume format (also known by the name of its international standard, ISO 9660). If you press a CD in this format, you can read it on a Macintosh, Apple IIGS, MS-DOS machine, and so on.

If you choose the High Sierra option, plan your data carefully, so that it can be read by many machines. For example, Microsoft Excel can share files with MS-DOS's Lotus 1-2-3. Hypercard uses a proprietary format that can only be used on the Macintosh, so it's not a good choice for a High Sierra CD.

For a good overview of CD-ROM technology, read the "AppleCD SC Developer's Guide," available from APDA. To find out what's available in CD titles, see the latest issues of the following magazines: CD-ROM Review, New Media, MacWEEK, MacUser, and MACWORLD.

To locate a vendor's address and phone numbers, use vendor name as a search string.

## AppleTalk: Problem with FastPath and Network Number Setting

Revised: 8/21/89  
Security: Everyone

AppleTalk: Problem with FastPath and Network Number Setting

=====

This article last reviewed: 22 June 1989

TOPIC -----

Here's a question concerning bridges and "Net" numbers. We have a 40-node AppleTalk network with six printers, an IBM 3270 gateway (Netway 1000), and a Kinetics FastPath 4.

When the FastPath is up, everyone's "Net" number (according to Inter-Poll) is 92 (in the AppleTalk zone). The Zone name is "applek". When the Kinetics is brought down, the devices that were on "Net = 92" are still set to 92. The Zone name goes away. If we turn on something new, it gets a Net of 0 and no Zone name, as one would expect. So, with the FastPath down, we have no Zone name, but everyone who has started up since the FastPath went down has a Net number of 0, and everyone who was running when the FastPath went down has a Net number of 92. When someone with a Net number 0 tries to print to a LaserWriter with a Net number of 92, a message is received that states that it can't find the LaserWriter.

So far, the only solution we have found is to restart all of the machines that have a Net number greater than 0. This is not acceptable. For the gateway, this involves bringing down the line, recycling the box, reloading it, and bringing up the mainframe line.

Because the Kinetics can send a broadcast to say that there is a bridge and that everyone should join Net number "x" when the bridge goes down, how can we reset the Net number to 0 without shutting all of the machines off? Is there a utility that would accomplish the task?

DISCUSSION -----

Apple Tech Comm knows of no way around this problem. Without a router, like the FastPath, operating on the network, there is no provision for getting (or setting) a network number on a machine. We are not aware of a utility that addresses this issue, and writing one would not be a trivial task.

If this is a recurring problem, the first issue that should be addressed is the FastPath going down so regularly. This should not be happening. When it does, bringing the FastPath up again would resolve the issue.

To address the window of time when the FastPath is down, you might consider setting the network number in the FastPath's configuration to zero. Although this will work for only one local network on an Internet, it would resolve the issue until the FastPath could be made to operate reliably.

## Ethernet Card: ROM Upgrade Is for Heavy Traffic Networks

Revised: 10/4/89  
Security: Everyone

Ethernet Card: ROM Upgrade Is for Heavy Traffic Networks

=====

This article last reviewed: 22 June 1989

TOPIC -----

There is a ROM upgrade available for the older Ethernet cards. Who should upgrade to the new ROMs?

DISCUSSION -----

Those who should upgrade are those who are connected to heavy traffic networks. Given that it is difficult to exactly define how much traffic is heavy traffic, Apple Tech Comm suggests a conservative approach when deciding if a network has heavy use. If a network is having no problems, there is little reason to upgrade.

To upgrade, customers should contact their service providers. They should have a service notice in their Service Programs Binder detailing which cards need upgrading and how to do the upgrade.

## HyperCard: How to Debug Too Much Recursion Error Message

Revised: 6/24/90  
Security: Everyone

HyperCard: How to Debug "Too Much Recursion" Error Message

=====

This article last reviewed: 22 June 1989

TOPIC -----

A user is having a "too much recursion" problem in a HyperCard stack that he is developing. The error occurs during a callback into HyperCard from an XCMD, which he wrote. He has checked his code for problems. Is there a way to determine what triggers the "too much recursion" message (like a traceback)?

DISCUSSION -----

We are not aware of any trace-back facilities available for HyperCard. HyperCard, itself, does not have the type of tracing needed here. Further, we could not locate any third-party add-ons available to resolve this problem.

To debug a problem of this sort, put information from the scripts and XCMDs you are using into debugging fields. This information usually includes a line per handler or XCMD call that includes the parameters being passed. When the recursion problem occurs, you then can inspect the trace that you have effectively created.

## MacWorkStation 3.0: Exec Questions & Answers (11/95)

Revised: 11/29/95  
Security: Everyone

MacWorkStation 3.0: Exec Questions & Answers (11/95)

Article Created: 21 August 1989  
Article Reviewed/Updated: 29 November 1995

TOPIC -----

This article answers the following questions about MacWorkStation 3.0:

- 1) Can I use SADE to debug my MacWorkStation exec modules?
- 2) Can I override MWS for mouse down events that are external to my\_exec window contents?
- 3) For the grow window instruction, can I define size\_rec?
- 4) Are exec construction rules the same as DAs in that the global data segment must = 0? If so, can I defeat some select global QuickDraw variables, such as ldgray and others?
- 5) I have written an exec that does not have a window. When a user generates a menu event, I trapped dosend, looked up record tp\_exec\_ref, and found that the xEvent field is 0 and has not recorded the modifier key.

DISCUSSION -----

It is important to equate MacWorkStation exec modules with FKEYs, HyperCard XCMDs, or INITs, not desk accessories. This understanding leads directly to some of the answers below.

- 1) Question: Can I use SADE to debug my MacWorkStation exec modules?

Answer: Currently, SADE cannot be used for debugging code segments, like MacWorkStation exec modules, FKEYs, or XCMDs.

- 2) Question: Can I override MWS for mouse down events that are external to

my\_exec window contents?

Answer: The Mouse command is only passed when a mouse down event occurs in the exec's window. You may be able to trap some of the mouse down events, only if you don't want to handle the event yourself, by trapping all sends and passing them through. However, this works only for those events that MacWorkStation determines it needs to generate a message to the host. A different option would be to implement an event loop in an exec module that trapped all of the events and then somehow caused MacWorkStation to deal only with specific events. This would definitely not be a trivial task.

3) Question: For the grow window instruction, can I define size\_rec?

Answer: This problem is similar to the one above in that MacWorkStation 3.0 does not provide access to this mechanism. This makes the process of intercepting and modifying this information difficult and likely to break in future releases of the product.

4) Question: Are exec construction rules the same as DAs in that the global data segment must = 0? If so, can I defeat some select global QuickDraw variables, such as ldgray and others?

Answer: Exec modules are restricted to a size of 32K, and they cannot access global data.

5) Question: I have written an exec that does not have a window. When a user generates a menu event, I trapped dosend, looked up record tp\_exec\_ref, and found that the xEvent field is 0 and has not recorded the modifier key.

Answer: xEvent is filled out only for the Active, Key, and Mouse commands passed to the Exec module.

## Xerox XNS-to-Macintosh Connectivity Solutions

Revised: 8/21/89  
Security: Everyone

Xerox XNS-to-Macintosh Connectivity Solutions

=====

This article last reviewed: 14 July 1989

TOPIC -----

Is there any way to connect a Macintosh to a Xerox network?

DISCUSSION -----

There are at least two ways to connect a Macintosh to a Xerox network. You can connect a Macintosh to a Xerox network through Xerox's ITS (Interactive Terminal Service), a serial interface to an 8000 server. ITS acts as a bulletin board service for users with PCs to call in to and access mail, file, and print capabilities of the network. You could set up a NetSerial or equivalent and log on via a terminal emulator to get access to the services required.

The other solution uses an asynchronous terminal emulator (like VersaTerm Pro). Connect the Macintosh modem port to an asynchronous terminal server (like Bridge Communications CS/1, CS/100, or other) and have the terminal server provide the XNS protocol services.

Terminal servers, like the Bridge Communications devices, provide a wide range of Ethernet/XNS services. This, combined with the Macintosh power, creates a very cost-effective solution.

For more details, search the Tech Info Library under "Bridge Communications" and "VersaTerm".

## System 6.0.3: Don't Use on Mac II Without SuperDrive (9/95)

Revised: 9/15/95  
Security: Everyone

System 6.0.3: Don't Use on Mac II Without SuperDrive (9/95)

Article Created: 21 August 1989  
Article Reviewed/Updated: 15 September 1995

TOPIC -----

Here is a report of multiple oddities about System 6.0.3 when used on a 68020 Macintosh II with two monitors and MultiFinder. If you display source or work on the second screen, several applications (including MS QuickBASIC 1.0, MacDraw 1.9.6, Capilano's DesignWorks 1.11, and MPW 2.0.2 and 3.0) hang the machine when saving or quitting. Note that the save operation is NOT completed before the crash.

Also, mounting a new volume when the last active window was on the secondary monitor occasionally causes an unusually long mount time, on the order of several minutes. (This may be due to a difficulty with building the desktop file). The system also hangs at shutdown, but only following directory changes (as when you move a file from one folder to another).

Admittedly, there were several (four or five) standard INITs in the System Folders on both the machines where the problems occurred. These are probably not a factor, because the problem went away immediately after reinstalling System 6.0.2. Because these were true work sessions, not debugging sessions, the sequence of operations that may have caused the difficulties is uncertain.

DISCUSSION -----

Apple Tech Comm has run and continues to run Macintosh IIs with multiple monitors under System 6.0.3 without experiencing the problems you reported. We have been running similar software and using it in similar fashions. This makes us suspect that there was some difference between your system configurations and ours.

If there was a problem with corrupted system software, removing and reinstalling the System and Finder would definitely have resolved the issue. It is possible for problems of this nature to manifest themselves on Macintosh IIs and not on Macintosh IIX or Macintosh IICX systems.

Although you stated that the INITs you were using are fairly standard INITs, we have seen problems caused by INITs, which you would not suspect as being the culprits. It is possible that one of these INITs does not work properly with System 6.0.3 and that was the root of the problem.

Unless you have an Apple SuperDrive (formerly Apple FDHD) upgrade in your Macintosh II, there is no reason to be running System 6.0.3--System 6.0.2 has the same functionality.

The FDHD/SuperDrive upgrade is no longer available.

## Tektronix 401x Terminal Emulator for Macintosh

Revised: 8/21/89  
Security: Everyone

Tektronix 401x Terminal Emulator for Macintosh

=====

This article last reviewed: 22 June 1989

TOPIC -----

Is there a Tektronix 401x terminal emulator for the Macintosh that works over a TCP/IP connection?

DISCUSSION -----

InterCon offers a TCP/IP Telnet/ftp product that supports VT240, Tektronix 4010/4014 graphics, and TN3270. Another solution is NCSA Telnet (version 2.2). This application also provides Tektronix 401x emulation, although it is not as well-advertised as InterCon's. NCSA Telnet is written by the National Center for SuperComputer Applications at the University of Illinois at Champaign-Urbana.

For more details, search the Tech Info Library under "InterCon" and "NCSA".

## LaserWriter: Adobe Font Metrics Information

Revised: 8/21/89  
Security: Everyone

LaserWriter: Adobe Font Metrics Information

=====

This article last reviewed: 22 June 1989

TOPIC -----

This article discusses how to set the actual size (the width and height) of the characters of the built-in fonts. These are the Adobe Font Metrics (AFM). The LaserWriter does not use true fonts for Bold, Italic, and so on. Instead it does some algorithmic calculation to create the these fonts from the plain typeface. This is where the discrepancies between the LaserWriter documents and some typesetting equipment appears. One typesetter uses the true Bold and Italics, and the LaserWriter uses algorithms. As a result, the documents are not quite the same.

DISCUSSION -----

Within PostScript, the shape of each character used in a given font is described in the Metrics for the character. There is no size associated with the character, only a description of how the character is to be drawn. The size of a character is set within a PostScript program using the command "scalefont".

For example: /Times-Roman findfont 12 scalefont setfont

Complete information on how PostScript fonts are scaled is in the "PostScript Language Reference Manual, ISBN #0-201-10174-2", Chapter 5, section 5.2, Organization and Use of Fonts.

The actual PostScript fonts used in the LaserWriter ROMs are available from Adobe as downloadable. When using the LaserWriter fonts in PostScript, the font type must be declared (Bold, Italic, Demi, and so on). Here is a list of the proper font names for the LaserWriter Plus:

Times-Roman  
Times-Bold  
Times-Italic

Times-BoldItalic  
Helvetica  
Helvetica-Bold  
Helvetica-Oblique

## TIFF: Caution - Not All TIFF Files are the Same

Revised: 6/15/92  
Security: Everyone

TIFF: Caution - Not All TIFF Files are the Same

Article Created: 22 June 1989  
Article Last Reviewed: 22 May 1992  
Article Last Updated:

### TOPIC -----

A user tried to copy a file created with MacView/AGFA Scanner for porting to Microsoft Windows, and it didn't work. Are there differences between the TIFF used on the Macintosh and the one used by Microsoft?

### DISCUSSION -----

The ability of applications to read TIFF files, created by another application, is based on the conformance of both applications to the TIFF specification, not the CPU type or operating system. Below is a copy of the TIFF Conformance Specification.

### Conformance -----

"Many of the application programs that read the contents of TIFF image files will not support all of the features described in this document. In some cases, little more than the default options will be supported. It is up to each organization to determine the costs and benefits associated with different levels of conformity. Therefore, claims of conformity to this specification should be interpreted with a certain amount of caution.

"It follows that the usage of this specification does not preclude the need for coordination between image file writers and image file readers. It is up to the application designer that initially writes a file in this format to verify that the desired file options are supported by the applications that will read the file."

To resolve this problem, contact the vendors of both products to confirm the conformance of the applications to the TIFF specification

AppleShare: What Determines the Volume Order In Chooser

=====

This article last reviewed: 22 June 1989

TOPIC -----

On a server with more than one volume, what determines the order of the volumes in the Chooser log-on sequence?

When our office server had only one volume, it obviously was the at the top of the list. When we added a CD-ROM drive, it took the top spot in the volume list. When I recently added a second hard drive to make it three volumes, it was inserted after the CD-ROM and before the startup volume. The startup volume is still last on the list.

DISCUSSION -----

Our tests and information provided by engineers involved in the development of the server revealed the following:

- At the server, devices are displayed in Finder order: startup volume first, followed by SCSI drives in descending order of SCSI address, followed by devices connected via the drive port in the order returned by the getVolInfo call.
- At the workstation, the devices are displayed in exactly the opposite order, placing the startup volume at the bottom of the list.

## AppleCD SC: Problem Mounting with Scanner and Macintosh IIX

Revised: 8/21/89  
Security: Everyone

AppleCD SC: Problem Mounting with Scanner and Macintosh IIX

=====

This article last reviewed: 22 June 1989

TOPIC -----

When I had an Apple Scanner and AppleCD SC attached to a Macintosh IIX, I couldn't get the AppleCD SC to mount a disk. Instead, I'd get the standard DIBadmount dialog box, which would ask me if I wanted to initialize the disk. I'm certain the AppleCD SC and Apple Scanner were properly cabled and all software correctly installed.

DISCUSSION -----

Apple Tech Comm has seen this problem, but cannot reliably reproduce it. In the past, we have been able to eliminate the problem by installing version 1.0 of the CD-ROM drivers, followed by reinstalling version 2.0 of the drivers. Recently, however, we learned that the problem could be caused by a faulty terminator. Replacing the terminator usually solves the problem.

## Logic Analyzer Controller: Gould Solution for the Macintosh II

Revised: 8/21/89  
Security: Everyone

Logic Analyzer Controller: Gould Solution for the Macintosh II

=====

This article last reviewed: 22 June 1989

TOPIC -----

This article describes Gould uses a Macintosh II as a controller for a multi-module logic analyzer.

DISCUSSION -----

In the January issue of Electronic Design, a new product from Gould Electronics was reviewed. Gould manufactures high-performance superminis often found in defense, electronic-development environments.

The new product is a very sophisticated, multi-unit "mainframe" logic analyzer controlled via SCSI by a Macintosh II. The Gould unit is a device that houses up to four independent logic analyzer modules (hence, "mainframe"). Each unit contains an instrument that can monitor and record up to 384 inputs from a system under test. The mainframe houses up to four of these. Each unit can be used separately or in conjunction with one or more of the other, optional units, allowing simultaneous analysis of up to four separate computer systems.

Analyzers connect to the system under test with two types of probes: the 96-channel Pyramid, which can run up to 10-nanosecond resolution (100 MHz), or the 16-channel Magnifying Glass, which does 1-nanosecond resolution (1 GigaHertz). These probes are intelligent devices that can be reconfigured graphically by the host Macintosh.

The article suggests that Gould Electronics viewed the Macintosh as the solution to a massive problem: normal logic analyzers are very complex to set up, control, and interpret and require quite an investment in time and patience. The user is prompted with dialog boxes as he selects functions he wants to enable. Individual inputs on the probes can be reconfigured in this manner as needed. Many other features make it an useful analytical tool.

Although not cheap, this may be the instrument of choice for the high-tech defense electronics lab, or the graduate electronics/computer science department that prefers to spend more time teaching the concepts and less time teaching an instrument.

## Apple Video Displays are Non-Interlaced

Revised: 8/21/89  
Security: Everyone

Apple Video Displays are Non-Interlaced

=====

This article last reviewed: 7 July 1989

TOPIC -----

An Apple user is looking at the new monitors and asked if they are interlaced. What is interlacing and do Apple Monitors have it?

DISCUSSION -----

Interlacing is a technique used on character-based displays to create solid character text. It is also used on home television sets, the dominant standard in the United States being NTSC. Using alternate scan lines, the monitor performs high-speed retraces to create the illusion that the monitor has twice as many lines as it does. A major drawback of interlaced displays is their tendency to noticeably flicker thin horizontal lines, lines that are frequently used on the Macintosh interface.

Macintosh displays assign pixels to scan lines on a one-to-one basis eliminating the need for interlacing.

There are several third-party scan converters available for the Macintosh that will output Macintosh non-interlace video as interlaced. For more information search on "NTSC" or "interlace".

## AppleShare: Why is there Activity When Opening Local Folders?

Revised: 8/21/89  
Security: Everyone

AppleShare: Why is there Activity When Opening Local Folders?

=====

This article last reviewed: 12 July 1989

TOPIC -----

Some users have noticed that when you open the Macintosh System Folder on the startup disk, the AppleShare network traffic arrows flash (sometimes causing a very long delay in opening the System Folder). This, of course, does not happen when AppleShare volumes are not mounted. Why does this happen?

DISCUSSION -----

When any folder is opened, the Finder checks the Creator of every file in that folder and looks in the Desktop file of the current volume to see if it can find a match. If there is no entry for that Creator type on the current volume, it continues to look through the Desktop file of each mounted volume until it finds an entry with a match to that Creator or until there are no more volumes.

Any file that appears in the Finder with the type of "document" when the folder is viewed by name or by date causes this to happen. This is because the Finder makes "document" the type, only if it doesn't have an entry for that Creator type in the Desktop file.

It is very common for applications to put files containing option settings in the System Folder. MacWrite and Microsoft Word both do this. MacWrite puts an unknown Creator type for that document. It, therefore, appears as "document" type. If you have any servers mounted whenever the System Folder is opened, selected, or redrawn, the servers are checked for an entry in the Desktop file matching the Creator type of the file.

Another case would be if you used an application on a server and created a document that you saved on your local disk. Whenever the folder containing that document is opened, the Finder searches the mounted volumes for the Creator of that document, because the local disk does not have an entry in the Desktop file to match it. Microsoft Word creates an options file,

which is put into your System Folder, with the Creator type of Microsoft Word. It, therefore, shows up as a Microsoft Word file. If, however, you don't have Microsoft Word on your local disk because you used an application from the server, when you open the System Folder again, the mounted servers are searched.

Once an application is copied to a volume, the Creator type of that application is saved in the Desktop file of that volume. Even if that application is removed from the volume, there is still an entry in the Desktop file of that volume for that application's Creator type. When the Desktop file is rebuilt, the old Desktop file is thrown away, and a new one is created. Immediately after the Desktop is rebuilt, the Desktop file will contain entries for every application on that volume.

A file that was created by an application that is no longer on the volume may not cause the Finder to search the desktops of other volumes for a Creator type, if there is still an entry in the Desktop file of that volume. For example, if you have Microsoft Word on your local disk, create a document, and later throw Microsoft Word away, the Desktop still will have an entry for Microsoft Word. The Finder will not search the desktops of other volumes. If the Desktop is rebuilt, the local Desktop no longer will contain an entry for Microsoft Word, and the Finder, therefore, will search the desktop of any mounted volumes.

## Apple IIGS: Cannot Access 3COM Server

Revised: 8/21/89  
Security: Everyone

Apple IIGS: Cannot Access 3COM Server

=====

This article last reviewed: 12 July 1989

TOPIC -----

A customer with an existing 3COM network wants to connect an Apple IIGS system and have access to the 3COM server. Is this possible?

DISCUSSION -----

To connect an Apple IIGS to a file server, the file server must be an AppleTalk Filing Protocol (AFP) file server. 3COM's file server is not an AFP file server. Their file server can coexist with AFP file servers but does not function as an AFP device.

The reason the server must use the AFP for the Apple IIGS is because software must be installed into the AppleShare File Server Admin application before the Apple IIGS recognizes the server. Because the 3COM file server uses its own network filing protocols, the Apple IIGS will not recognize the 3COM server.

The Apple IIGS can be attached to a LocalTalk network that is connected to the 3COM server, but it will not be able to access the 3COM server. If there are LaserWriters on the LocalTalk network, the Apple IIGS can print to them.

Until 3COM's file server is seen as an AFP server by the AppleTalk, a way to provide file service from 3COM to the Apple IIGS seems unlikely.

## Macintosh-to-IBM 2780/3780 Connectivity

Revised: 8/21/89  
Security: Everyone

Macintosh-to-IBM 2780/3780 Connectivity

=====

This article last reviewed: 14 July 1989

TOPIC -----

Are you aware of any method for connecting a Macintosh to IBM 2780 and 3780 machines? Apparently, they are an old series of mainframe/mini. They take the BACS operating system and are used in the U.K. in the banking sector.

DISCUSSION -----

Cleo Software's Mac-3780Plus SSM from Cleo Software is a complete, Macintosh hardware/software package designed to emulate an IBM 2780 or 3780 terminal.

Files can be transferred to any other micro, mini, or mainframe that supports the IBM 2780/3780 BSC (Binary Synchronous Communications or Bisynchronous) protocol. Files can be stored, processed, or printed. Files received from another 2780/3780 device can be printed, saved to disk, or displayed on the console.

The package has a menu format for

- interactive execution
- job file
- log file support for unattended operation
- a line trace monitor for diagnostics
- a "System" command for executing local programs without leaving communications.

For more details, search the Tech Info Library under "CLEO Software".

## Microsoft Windows: LaserWriter Compatibility

Revised: 3/4/90  
Security: Everyone

Microsoft Windows: LaserWriter Compatibility

=====

This article last reviewed: 13 October 1989

TOPIC -----

Is it true that Microsoft's "Windows" needs ROM 2.0 or greater present in the LaserWriter IINTX to function properly. Is there another issue here?

DISCUSSION -----

The issue is not the version of the ROM but the version of PostScript residing in the ROMs. The original LaserWriters started with ROM version 1 or PostScript version 23. The second ROM set for the original LaserWriters is known as ROM version 2 or PostScript version 38. The third ROM set is known ROM version 3 or PostScript version 47.

The LaserWriter IINT and LaserWriter IINTX both use PostScript version 47. However, the ROMs in the LaserWriter IINT and LaserWriter IINTX have additions to the ROMs, which are in the original LaserWriters. The ROMs in the LaserWriter IINT and LaserWriter IINTX are considered ROM version 1.0 for the LaserWriter IINT and LaserWriter IINTX, although the PostScript version is 47.

Microsoft Windows requires PostScript version 38. In the older LaserWriters, version 38 of PostScript was also known as version 2 of the ROM.

The latest versions of Windows (Windows 2.11) and its PostScript driver (PostScript driver 3.1) do not suffer from this problem and will print to a LaserWriter II successfully.

Apple Two-Page Monitor: Correction to Slot Info in Manual

=====

This article last reviewed: 12 July 1989

TOPIC -----

The documentation for the Apple Two-Page Monochrome Monitor states that the video card must be the card closest to the power supply. Is this necessary, and, if so, why?

DISCUSSION -----

The manual for the Apple Two-Page Monochrome Monitor is incorrect. You can put the video card in any slot. This statement will be removed from the manual in its next revision.

## MultiTalk: No Longer Available for AppleTalk Network

Revised: 8/21/89  
Security: Everyone

MultiTalk: No Longer Available for AppleTalk Network

=====

This article last reviewed: 12 July 1989

TOPIC -----

Abaton discontinued distribution of MultiTalk in late spring 1988. The following is a brief description of MultiTalk and known incompatibilities:

DISCUSSION -----

MultiTalk lets AppleTalk network users share serial devices. It has four mini-circular-8 connectors: one for AppleTalk (RS-422) and three for RS-232. The RS-232 connectors support modems, scanners, plotters, printers, or protocol converters. The user can select from four ports when the modem port is logically selected, and there can be up to four MultiTalks per zone.

MultiTalk is incompatible with MacLink Plus, Switcher (intermittent), Telescape Pro.

MultiTalk fails to cause DTR to drop on disconnect when using VersaTerm.

## PostScript: How To Modify LaserWriter Character Sets

Revised: 8/21/89  
Security: Everyone

PostScript: How To Modify LaserWriter Character Sets

=====

This article last reviewed: 12 July 1989

TOPIC -----

In each of the Adobe fonts contained in the ROMs of the LaserWriter IINT, there are three types of characters that some users (especially in high-end publishing) need. The three characters are: uppercase and lowercase "thorn", uppercase and lowercase "eth", and a "agoneck."

These characters cannot be seen in Key Caps but are printable from a PC connected to the LaserWriter IINT. When the PostScript code is sent directly to the printer, it works. However, the user needs to print from a word processor. When trying to print from Microsoft Word, the encoding vector in the Laser Prep file does not allow these characters. Here is additional information:

PostScript codes for characters (ref. ISO 6973)

/thorn 374 Octal  
/THORN 354 Octal

/eth 342 Octal  
/ETH 363 Octal

/agoneck 254 Octal

DISCUSSION -----

According to PostScript documentation, and after having interrogated the LaserWriter's complete character sets, Apple Tech Comm has determined that the thorn, THORN, eth, ETH, and agoneck characters are not encoded by the Laser Prep file. However, the user can create these required characters by using one of two methods. The first method is the more complicated of the two and requires modifying the Laser Prep file with ResEdit.

Method #1

-----

Any modifications to the System file and Laser Prep file should be made using copies of the files. Once the modifications have been successfully completed, then the original System file and Laser Prep file can be replaced with the modified files.

Using ResEdit, follow these steps to encode the required characters:

- 1) Determine what characters are currently available (using Key Caps), but seldom, if ever, used. These will be the characters that you will replace with the thorn, THORN, eth, ETH, and agoneck.
- 2) Using ResEdit, open the Laser Prep file and POST resource. Locate POST resource -8181 (this is the resource that encodes and maps special characters) and open it as type "STR#" using the "Open As..." menu item.
- 3) Starting at the 8th string, the special characters are encoded by name. Locate the characters, by name, that you determined were not used in step 1.
- 4) One at a time, select the name of the character to be substituted and type the name of the new character (thorn, THORN, eth, ETH, and agoneck).
- 5) Close the resource and the Laser Prep file and answer "YES" to save the changes.
- 6) Open the System file, select and open the FONT resource, and select the font(s) you want to display the thorn, THORN, eth, ETH, and agoneck characters.
- 7) Edit the substituted characters in the fonts to match the new characters.
- 8) Close the resource and the System file and answer "YES" to save the changes.

The Laser Prep file and System file now have been edited to allow the use of the thorn, THORN, eth, ETH, and agoneck characters. They will be recognized by all LaserWriter fonts.

Note: The LaserWriter must be initialized with this new Laser Prep file for the modified font dictionary to be invoked (turn the LaserWriter off and back on). Ensure that the system with the modified Laser Prep file is the first system to print to the printer.

Method #2

-----

The second method is to use a third-party laser font utility. One of the more popular laser font utilities is Fontographer 2.4 from Altsys Corp. For more details, search the Tech Info Library under "Altsys Corp." Here is a description of Fontographer:

Fontographer is a professional outline font editor for the Macintosh computer and PostScript printers. Using Fontographer, you can create a professional-quality PostScript font in hours. When complete, your font can be printed on Apple's LaserWriter, LaserWriter Plus, or any PostScript-compatible device. The characters are defined with cubic Bezier curves and straight lines, so your characters look good at any size or resolution from 300 dot-per-inch laser printers to 2450 dot-per-inch typesetting machines.

Fontographer fonts work just like the standard built-in LaserWriter fonts to give you fast, high-resolution printing. Bitmap fonts can be generated automatically. A copy of FONTastic font editor is included to perform the final fine-tuning of your bitmap fonts for screen display.

## Apple Presents..: Problem Installing on Corvus Net

Revised: 8/21/89  
Security: Everyone

"Apple Presents..": Problem Installing on Corvus Net

=====

This article last reviewed: 14 July 1989

TOPIC -----

This article concerns a school lab consisting of Apple IIGS systems and a Corvus server running Constellation 3 software. The school was able to load the "Apple Presents Apple" disk on the server and run the program by making the following modifications:

- 1) They copied SYSTEM.PASCAL into the keyboard volume.
- 2) They modified the SYSTEM.LIBRARY by copying LONGINTI, TRANSCEN, and RTUNIT into the SYSTEM.LIBRARY.

They would like to load the "Apple Presents the Apple IIe, An Introduction" disk (Pascal-based, 1984, 691-0020-A) and run the program from the Corvus, too. The procedure they used for the "Apple Presents Apple" disk does not seem to work for this disk. What should they do?

DISCUSSION -----

There are several issues involved when installing the "Apple Presents.." (691-0020) disk on the Corvus network:

- 1) The disk they successfully installed was a Pascal 1.0 disk, while the one they are trying to install is Pascal 1.2-based.
- 2) Each of the "Apple Presents.." disks was created for a specific purpose and may or may not use a standard version of the Run Time system.
- 3) Here's the most important one: the SYSTEM.LIBRARY file for the "Apple Presents.." (691-0020) disk contains the following units:

| Unit No. | Unit Name | Size |
|----------|-----------|------|
| -----    | -----     | ---- |

|    |          |      |
|----|----------|------|
| 20 | SHORTGRA | 3144 |
| 21 | SHORTGRA | 18   |
| 26 | INTROLIB | 6598 |
| 27 | INTROLIB | 5696 |
| 25 | TYPE1UNI | 1518 |
| 23 | TYPE2UNI | 4426 |
| 24 | TYPE3UNI | 317  |

and the SYSTEM.LIBRARY file for the successfully installed "Apple Presents.." disk contains the following units:

| Unit No. | Unit Name | Size |
|----------|-----------|------|
| -----    | -----     | ---- |
| 31       | PASCALIO  | 2082 |
| 28       | CHAINSTU  | 212  |
| 20       | TURTLEGR  | 3108 |
| 21       | TURTLEGR  | 18   |
| 22       | APPLESTU  | 678  |
| 26       | INTROLIB  | 2072 |
| 27       | INTROLIB  | 1642 |

What does this mean to the school? Notice that both libraries contain two units named "INTROLIB". Unfortunately, the library used on the disk that they school was able to install on the network is private. That is, it has no interface section). This is a trick used by developers to protect their code.

Most of the "Apple Presents.." software was created under contract, and Apple doesn't own the code. If the school is still interested in installing both of these packages on the network, they should combine the two libraries using the INTROLIB from the "Apple Presents.." (691-0020) disk. This may or may not work; Tech Comm can't duplicate the Corvus network, because Corvus is out of business.

The school might also look at the "Apple Presents.." disks that come with the Apple IIc Plus. These packages are fairly generic and are ProDOS-based. The school may have better luck installing them on the network.

## LaserWriter Family: Hammermill Paper Smudging Problem

Revised: 8/21/89  
Security: Everyone

LaserWriter Family: Hammermill Paper Smudging Problem

=====

This article last reviewed: 14 July 1989

TOPIC -----

This article discusses how to tell non-smudging Hammermill "Laser Plus" paper from earlier papers that exhibited smudging problems.

DISCUSSION -----

Hammermill Paper initiated a process change at the end of 1988 with its "Laser Plus" paper. This change led to some smudging when printing to Apple LaserWriter printers. In 1989, the process was again changed to correct this situation. All paper manufactured in 1989 should work without any problem.

You can identify paper that is manufactured in 1989 by looking at the ream number, which is printed in black ink on the top of the ream. If there is a "J" in the ream number, about midway, then it was manufactured in 1989. An "I" indicates a 1988 manufacturing date, and paper that may cause smudging.

## ADA Programming Capabilities for the Macintosh

Revised: 8/21/89  
Security: Everyone

ADA Programming Capabilities for the Macintosh

=====

This article last reviewed: 14 July 1989

TOPIC -----

Is there a compiler that provides ADA programming capabilities for Macintosh computers? Currently, the only two suppliers of such a product that I know of are Alsys and Meridian. The Alsys product currently runs under A/UX only. I understand that the Meridian product runs under Macintosh OS.

DISCUSSION -----

AdaVantage is the product you're probably referring to. Note that it will become available from APDA in the future. For a more complete description of the product, contact Meridian or see the product description in the Macintosh Buyer's Guide: A Redgate Publication, Winter 1989.

AdaVantage Compiler 2.2

-----

Minimum Configuration: Macintosh Plus, 2MB RAM, 20MB hard disk drive,  
MPW C.

The AdaVantage compiler provides ADA programming capabilities for Macintosh computers. An optional debugger and code optimizer are available.

Standard features:

- provides support for full generics, tasking, and separate compilation
- provides all standard packages
- implements most of the implementation-dependent system programming facilities (ANSI/MIL-STD-1815A Chapter 13)
- includes a set of library management tools that provide control over programming project organization and databases of compilation units
- includes auxiliary directory arrangements that permit separation of source code and compiler-generated files.

The optional Meridian AdaVantage Optimizer improves code output by providing constant expression evaluation, dead code removal, jump optimizations, common subexpression elimination, strength reduction, and unused program removal.

The optional Meridian AdaVantage Debugger provides an interactive source-level debugging capability. The debugger supports breakpoints, subprogram traces, single-stepping, subprogram callback traces, and full ADA variable reference syntax.

The AdaVantage compiler is supplied on four disks. Included are:

- the compiler
- a high-level linker
- library management tools
- standard support packages
- additional I/O packages
- run-time object libraries

For more details, search the Tech Info Library under "Meridian Software Systems".

## AppleTalk: Connecting to Phone Company New Advanced Services

Revised: 7/23/92  
Security: Everyone

AppleTalk: Connecting to Phone Company New Advanced Services

=====

Article Created: 21 August 1989  
Article Last Reviewed: 14 July 1989  
Article Last Updated: 22 June 1992

TOPIC -----

A customer wants to route AppleTalk into what sounds like an ISDN circuit. Pacific Bell is offering a new service called "Advanced Digital Network" (ADN). This new topology is ready through central offices, and the charge has been approved by the California Public Utilities Commission.

The circuit end points require a third-party device called CSU/DSU (Customer Service Unit/Digital Service Unit).

- 1) Whose CSU/DSU works?
- 2) How do I get AppleTalk into the CSU/DSU?

DISCUSSION -----

ADN is a new Pacific Bell Telephone service facilitating high-speed point-to-point communication. It is a 64K digitized voice or 56K bps data DDS (Digital Data Service) line incorporating new, digital, cross switches. These switches are better suited to high-speed digital transmissions than to sending digital information modulated on carrier signals over standard, public, telephone, voice-communication circuits. Note that this service is currently marketed under many different names by other common carriers.

DSU stands for "Data Service Unit," which is the interface to the ADN. It is somewhat analogous to a "digital" modem. The DSUs translate the computer's unipolar serial data to baseband bipolar signals. The DSU uses a DCE interface to communicate with the terminal, and then transmits the data in a special format over the ADN.

CSU ("Channel Service Unit") is sometimes required at the end of some links. The trend today is to incorporate the CSU into the DSU.

AT&T offers many types of DSUs/CSUs. They vary by the data rates they support for use in stand-alone or multiple-mount installations. Installations can run short distances point-to-point in a building or campus environment using LADS ("Local Area Data Sets"), using DSU units, CSU units or combinations of both. These units usually conform to EIA RS-232-C standards, with data and clock signals that meet CCITT V.35. The DSU DCE-to-terminal interface is full duplex.

Routing AppleTalk packets over ADN should be straightforward. You need an AppleTalk bridge between the Macintosh and DSU. Because the AppleTalk bridges are asynchronous, you also need a commonly-available, asynchronous-to-synchronous converter between the bridge and DSU. Among the bridges, only Telebridge supports data rates up to 57,600 bps; R-Server currently supports up to 19.2K bps. You could substitute an Ethernet bridge for the AppleTalk bridge above if using EtherTalk.

Apple uses many types of links, including Ethernet, LocalTalk, T-1, and fiber. We are not presently using ADN. Data rates can be much higher using T-1 or ISDN lines as compared to ADN.

ISDN lines are not yet a "tariff" service; they are not priced by the California Public Utilities Commission. This doesn't mean ISDN lines are not available. They are and are acquired via contracts, usually making them less cost-effective presently than other services. Additionally, ISDN interfaces are not yet commercially available for the Macintosh.

Because Pacific Bell offers intrastate service, the account may need to contact MCI or AT&T, for instance, to discuss interstate services.

For more details, search the Tech Info Library under "Shiva Corp".

## Motorola 2000-to-Macintosh Connectivity

Revised: 8/21/89  
Security: Everyone

Motorola 2000-to-Macintosh Connectivity

=====

This article last reviewed: 14 July 1989

TOPIC -----

Is there any way to emulate a Motorola 2000 terminal?

DISCUSSION -----

Terminals connected to the Motorola 2000 are very basic and can be configured for baud rate, data bits, stop bits, and parity. The port can be configured for either RS-232 or RS-422. It shouldn't require any special out-of-the ordinary protocols. All of this means that almost any multipurpose terminal emulation program for the Macintosh can be used to connect to a Motorola 2000.

## Apple IIGS: How to Access the Clock

Revised: 8/21/89  
Security: Everyone

Apple IIGS: How to Access the Clock

=====

This article last reviewed: 14 July 1989

TOPIC -----

I have a customer using Z-BASIC on his Apple IIGS under ProDOS, running as an Apple IIe. Although there are no toolbox calls for accessing the Apple IIGS clock from Z-BASIC, is there a way to do this from Z-BASIC with PEEKS and POKES or a machine language call?

DISCUSSION -----

The preferred method is to use the ProDOS GET\_TIME call. Note: You need ProDOS 8 version 1.2 or later to get the time on the Apple IIGS.

This method works on any Apple II running under ProDOS and with most Apple II-compatible clocks (because they all come with ProDOS patch routines). More information on the format of the GET\_TIME call and other ProDOS commands is in the ProDOS Technical Reference Manual. The GET\_TIME call is documented on page 71. Additional information is on page 99 and pages 104 through 106.

When the GET\_TIME routine is called, the system date and time are placed into the documented locations. Using PEEKs, the data in those locations can be extracted.

## Apple IIGS: How To Print to a LaserWriter

Revised: 8/21/89  
Security: Everyone

Apple IIGS: How To Print to a LaserWriter

=====

This article last reviewed: 14 July 1989

TOPIC -----

A person using Music Writer software on an Apple IIGS wants to print to a LaserWriter IINTX in the Sonata font, which Music Writer uses. How do you do this? Can you use fonts other than Courier and Times with AppleWorks 2.0?

DISCUSSION -----

Music Writer uses Pyware's own music font. It is similar to Adobe's Sonata font, but not from Adobe. The font is included with Music Writer. To print to any member of the PostScript LaserWriter family, make the usual ProDOS 16 or GS/OS printer choice. Then, from Music Writer, select the print command. The musical score then can be printed on the LaserWriter.

To use other fonts with AppleWorks requires PostScript programming knowledge. Beyond the changes mentioned, font selection for ProDOS 8 applications relies on changing the ImageWriter Emulator (IWEM) PostScript code. The font to be used is designated within the IWEM downloadable PostScript file.

## MARS: Multimedia Color Database for the Macintosh (9/93)

Revised: 9/2/93  
Security: Everyone

MARS: Multimedia Color Database for the Macintosh (9/93)

=====  
Article Created: 21 August 1993  
Article Reviewed/Updated: 2 September 1993

TOPIC -----

I want to implement a database of color images that can be accessed locally or remotely. I'm flexible as to how these images can be input (scanned photos, videotape, and so on). Any suggestions?

DISCUSSION -----

MARS (Multi-User Archival and Retrieval System) from MicroDynamics, Ltd. offers one solution. MARS can take input from any kind of document through an appropriate scanner. The documents are then stored on WORM (Write Once Read Many) optical disks. These documents can be used over and over again, but the original can never be changed.

The system also has OCR (Optical Character Recognition) capability, that lets you convert any digitized document to text and then edit it with a word processor. You can add these revised documents to the optical disk.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

## HyperCard: How to Configure for Modem Dialing

Revised: 8/21/89  
Security: Everyone

HyperCard: How to Configure for Modem Dialing

=====

This article last reviewed: 14 July 1989

TOPIC -----

Can the phone-dialing portion of HyperCard support 9600-bps modems? Also, can HyperCard dial out through an internal modem, like an Epic 2400?

DISCUSSION -----

HyperCard's dial command is designed for voice-only calls. There is no support for data communications with the dial command.

If the 9600-bps modem is a Hayes command set-compatible modem, HyperCard can dial the modem.

The dial command is only applicable to the Macintosh speaker/audio port or to a modem attached to the serial port. HyperCard requires an XCMD or XFCN to recognize a NuBus modem.

If you want to do data communications after dialling, you need a different approach is required. The HyperCard Serial Communications Toolkit, available from APDA, makes HyperCard dialing and data communications possible.

Another option for data communications is a set of external commands and code resources called FITOS from MITEM Corporation. These include a number of different terminal emulators. The advantage of this package is that it handles everything except the actual information that would normally be presented to the user. You don't have to be concerned about the communications protocols used or the terminal formatting characters sent by the host. The possible disadvantage is that if it does not support the type of terminal that you need it to support, you have to deal with the terminal emulation yourself.

For data communications with NuBus modems, you need XCMDs and/or XFCNs designed

for NuBus modems. Apple Tech Comm does not know of any XCMD or XFCN available for the internals modems.

For more details, search the Tech Info Library under "MITEM Corporation".

## Macintosh: How to Increase the Maximum Number of Open Files

Revised: 8/21/89  
Security: Everyone

Macintosh: How to Increase the Maximum Number of Open Files

=====

This article last reviewed: 14 July 1989

TOPIC -----

How does one change the number of concurrent files open at the same time under the Macintosh OS?

DISCUSSION -----

(Important: Any modification to boot block information is not supported by Apple.)

The SystemStartup information (for a Macintosh system or a file server), is stored in logical blocks 0 and 1 of an HFS startup disk. It contains the maximum number of files that can be open simultaneously. This is currently set to 10. The location for this parameter is \$7A of logical block 0 on an HFS disk. The number at \$7A (default is \$000A or Decimal 10) serves as the parameter for files open at one time.

The number \$000A (or Decimal 10), for instance, is proper for 128K and 512K systems. If the Macintosh is equipped with 1MB or more of memory, the system multiplies the number at \$7A by four (that is, it becomes decimal 40) and uses the new number as the new file limiter.

You can use a disk editor, like FEdit, to change this number. The File Control Block Buffer and System Heap size will be calculated with the changed files open parameter upon restarting.

If you must raise this number, do it in small increments. Raising the number in location \$7A, as some users have done, can force the system to set aside too much memory. This causes a system error, which, because it is unexpected, the system cannot handle. The result is a system lockup.

Tech Note 113 also relates to the topic.

Note: FoxBase allows a maximum of 48 open files, regardless of how many the Macintosh OS allows.

## 8775 Terminal Emulator: None Yet Available for the Macintosh

Revised: 4/11/91  
Security: Everyone

8775 Terminal Emulator: None Yet Available for the Macintosh

=====

This article last reviewed: 19 July 1989

TOPIC -----

Have you heard of Macintoshes connected to an IBM 8100 mini-computer using 8775 terminal?

DISCUSSION -----

Apple Tech Comm does not know of any 8775 terminal emulators available for the Macintosh.

The 8775 Display Terminal is a high-function, single-station, cathode-ray tube, microprocessor-controlled terminal that provides a means of entering data to, and receiving data from, the 8100 Information System and System/370, 30XX, and 4300.

It is available in four models. The base 8775 offers equivalent function to 3276/3278 display units. The other models offer differing connection options.

## VAX: How To Print to a LaserWriter Connected to a Terminal

Revised: 3/4/90  
Security: Everyone

VAX: How To Print to a LaserWriter Connected to a Terminal

=====

This article last reviewed: 19 July 1989

TOPIC -----

Many applications for VAX systems, such as All-in-1, let the host program print to a printer that is connected to the terminal. This is called pass-through printing and was a feature of the old VT102 terminals; it is still a part of the newest DEC terminals.

Is there a Macintosh terminal emulation product that allows a VAX program to access a networked LaserWriter in this fashion? There are several options for setting up a LaserWriter as a system printer, but is it also possible to emulate a printer that is connected to the user's terminal?

DISCUSSION -----

There are some Macintosh terminal emulation products that echo the output being sent to the terminal to a printer. The printer support for this is limited to printers connected directly to the Macintosh acting as the terminal. This prohibits the use of the LaserWriter over AppleTalk for this purpose.

The type of printer for which this pass-through printing is intended is a printer that prints one character at a time as opposed to one page at a time. The LaserWriter prints one page at a time.

MicroPhone II from Software Ventures and Red Ryder 10.0 from The FreeSoft Company come close to providing this functionality. They have the ability to turn printing on and off. When printing is on, they buffer the output until you turn printing off. At that point, they send the output one page at a time to the LaserWriter.

## AppleFax Modem: How To Use as 9600-Baud Modem

Revised: 8/21/89  
Security: Everyone

AppleFax Modem: How To Use as 9600-Baud Modem

=====

This article last reviewed: 19 July 1989

TOPIC -----

The AppleFax Modem manual implies that the modem allows a Macintosh file to be transferred from one Macintosh to another Macintosh via two AppleFax Modems at 9600 baud. Is this accurate?

DISCUSSION -----

Page 92 of the "AppleFax Modem User's Guide" states the following:

"If you want, you can use a communications application as long as you're communicating with another AppleFax Modem. A communications application lets you transmit Macintosh files, type messages back and forth, and use the modem commands described in Appendix B."

The manual goes on to say (on page 92) what communications parameters the AppleFax Modem requires for successful use a 9600-baud modem.

This means that the AppleFax Modem allows you to transmit Macintosh files (text files, MacPaint files, PICT files, and so on) to another Macintosh at 9600 baud as long as both modems are AppleFax Modems. It is not necessary for both AppleFax Modems to be using the same communications software as long they support the same transfer protocol.

The AppleFax Modem does support a subset of the Hayes "AT" command set. For more information on this, look in Appendix B, which starts on page 137.

## Macintosh: Using Wrong System Installer Causes Color Problems

Revised: 8/21/89  
Security: Everyone

Macintosh: Using Wrong System Installer Causes Color Problems

=====

This article last reviewed: 20 July 1989

TOPIC -----

A user installs the System on a Macintosh IICx attached to a color monitor with either 16 or 256 colors selected. The monitor shows a color desktop, but the Apple and Macintosh icons remains black and white. The typical diagnosis is a hardware problem with the monitor or video card.

DISCUSSION -----

The problem lies with the choice of installation disks. Using the Utilities One disk to install the System instead of the System Tools disk causes this problem. The Utilities One disk contains the minimum Installer scripts, which do not include the color Apple icon, or the color Macintosh icon (which appears in the "Welcome to Macintosh" startup dialog), among other things.

Use the System Tools disk included in the new "Open Me First" package that ships with the Macintosh IICx, not the Utilities One disk that is in the traditional place we have put system disks. This installs a complete system, including the color icons.

## A/UX 1.1: Solution for loop:bad value Error

Revised: 11/10/92  
Security: Everyone

A/UX 1.1: Solution for "loop:bad value" Error

=====

Article Created: 20 July 1989

### Article Change History

-----

08/31/92 - REVIEWED

- For technical accuracy.

### TOPIC -----

A user gets the message

"loop:bad value"

before the Ethernet messages  
on A/UX startup. All Ethernet communications work well. Is this message  
related to Ethernet, or something else?

### DISCUSSION -----

This error message comes from the startup script BNET in /etc/startup.d.  
It can be caused by an incorrect entry in the /etc/hosts file for the loop  
address. The line for the loop address should look like this:

```
127.0.0.1    loop  loo  lo    localhost    Software_Loopback
```

## A/UX 1.1: toolboxdaemon Problem Solved

Revised: 9/3/92  
Security: Everyone

A/UX 1.1: "toolboxdaemon" Problem Solved

=====

Article Created: 21 August 1989

Article Change History

-----

08/31/92 - REVIEWED

•For technical accuracy

TOPIC -----

I can't seem to get the toolboxdaemon to run correctly in the release version. I have set the command in the inittab file to "once" and restarted. When I try to run HFX, I get messages saying that the toolboxdaemon seems to be dead and fatal toolbox error. I also tried the newunix toolbox command and restarted. That didn't help. Next, I put a command in the /etc/startup file to automatically run toolboxdaemon in the background. Everything seems OK until I quit from HFX. Instead of seeing the console screen, I get a series of tiny "windows" across the screen. I can type in commands, but I can't read them. What's wrong?

DISCUSSION -----

The first error message appears when a toolbox application is started, and the toolboxdaemon is not running. The entry in the /etc/inittab file is correct when set to once, but the toolboxdaemon won't be started, unless the system is brought into multi-user mode with the command:

```
init 2
```

The reason for the tiny windows is that the system is running in color mode under the toolbox application and is trying to talk to a monochrome display (the A/UX console) when the error occurs. Try running the system in monochrome mode so that you can read the error message being sent to the screen.

## LaserWriter: How To Restore Factory Defaults

Revised: 3/5/92  
Security: Everyone

LaserWriter: How To Restore Factory Defaults

=====

Article Created: 21 August 1989  
Article Last Reviewed: 5 March 1992  
Article Last Updated: 5 March 1992

TOPIC -----

A user modified some of their LaserWriter's persistent parameters through PostScript commands. They would now like to restore all settings to the factory defaults. Is there a PostScript command to do this?

DISCUSSION -----

There is no standard command within the PostScript language to reset all parameters to the default settings. However, it is possible to write a PostScript program that, when downloaded to the LaserWriter, resets each parameter individually to its default settings. Since a number of persistent parameters are product specific, this program would have to be modified for each LaserWriter model: the LaserWriter, LaserWriter Plus, LaserWriter IINT and NTX, and the Personal LaserWriter NT.

The LaserWriter IIx and IIg do have the ability to restore factory defaults through a single command. This is a device specific feature, and will not work on earlier LaserWriter models. The following PostScript program will restore the factory defaults of either a LaserWriter IIx or IIg.

```
0 serverdict begin exitserver
<< /FactoryDefaults true >> setsystemparams
systemdict begin
realtime 10000 add
{ dup realtime le { pop exit } if } loop
quit
```

To send this program to your LaserWriter, copy and paste it into a blank TeachText document. Save the result, and download it with the LaserWriter Utility's "Download PostScript File" feature.

## ..TIL04167-LaserWriter-How\_To\_Restore\_Factory\_Defaults\_(TA40164).pdf

Note that the user definable settings for push-wheel positions 6-9 will also revert to their defaults after the program is downloaded. This means you must be careful if the LaserWriter is connected to a LocalTalk network and you reset the defaults. If the default type for the mini-8 port at the current push-wheel setting isn't LocalTalk, resetting the defaults will disable your ability to communicate with the LaserWriter and can disrupt network traffic.

## A/UX 1.1: SCSI Block Access

Revised: 9/16/92  
Security: Everyone

A/UX 1.1: SCSI Block Access

=====

Article Created: 10 July 1989

### Article Change History

-----

08/27/92 - REVIEWED

- For technical accuracy.

### TOPIC -----

A customer wants some information on block read/write functions in A/UX 1.1. She mentioned library files, like "ncr5380" and "ncr5380.h", as examples. Are there generic SCSI libraries?

### DISCUSSION -----

Apple Tech Comm could not locate generic SCSI libraries in the distributed A/UX binary. All device drivers and related routines are imbedded in the A/UX kernel. The only header files related to SCSI and the NCR 5380 SCSI chip are in the /usr/include/sys directory. These are:

ncr.h - interface to NCR 5380 SCSI chip  
ncr5380.h - interface to NCR 5380 SCSI chip and SCSI manager  
SCSI\*.h - generic SCSI driver interface header files

As an alternative, the customer might get an A/UX Device Drivers Kit from APDA. The kit includes the driver source code files, routines, samples, and detailed information on how to build and install a device driver into the kernel.

## Macintosh: Databases with Graphics Capability

Revised: 2/12/93  
Security: Everyone

Macintosh: Databases with Graphics Capability

Article Created: 21 August 1989

### Article Change History

02/12/93 - UPDATED

- Fox Software, Inc. acquired by Microsoft Corporation

### TOPIC -----

What database products for the Macintosh support a field type for vector graphic objects?

### DISCUSSION -----

We assume that what you mean by vector graphic objects is anything other than bitmapped objects. The PICT format is one example of a non-bitmapped graphics file. If our assumption is correct, then you have a few solutions. If this is not the case, we'll need to know specific details about the format of the graphic object and the application that created it. Even within a single file format there are often slight variations used by different applications that can cause strange incompatibilities, so it's difficult to give a simple answer to this kind of question.

PictureBase, from Symmetry Corp., is a database that manages pictures. It can store both bitmapped images and PICT images. It lets you pull up these images and search by keywords (which you input for each picture) or by words in the filename. No other kinds of data can be stored along with the picture.

FoxBase+/Mac, from Microsoft Corporation, also lets you store PICT images and bitmapped images. This is a full-blown database that handles pictures as a field type. It also has character, numeric, date, logical, and memo field types. This information can be manipulated in many ways, which is typical of a relational database management system.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

## Apple IIGS: Printing to Legal-Size Paper From AppleWorks

Revised: 8/21/89  
Security: Everyone

Apple IIGS: Printing to Legal-Size Paper From AppleWorks

=====

This article last reviewed: 20 July 1989

TOPIC -----

A user is having problems printing to a LaserWriter from AppleWorks (on an Apple IIGS). He can print on letter-size paper but not legal. He has a legal tray and has set the paper length to Legal in AppleWorks. Does AppleWorks on an Apple II support legal printing from a LaserWriter?

DISCUSSION -----

If you print in an AppleWorks 2.0 and ProDOS 8 environment, the ImageWriter Emulator (IWEM) does not support legal-size paper; it supports only letter-size paper. IWEM is not alone; the LaserWriter Diablo 630 emulator does not support paper lengths longer than 11 inches.

However, if you try this in AppleWorks on an Apple IIGS with GS/OS environment, everything works smoothly and with the desired results. In addition, the user can select various fonts and styles in AppleWorks for more pleasing results.

## MacTCP: Comparison to Kinetics K-Talk

Revised: 12/4/89  
Security: Everyone

MacTCP: Comparison to Kinetics K-Talk

=====

This article last reviewed: 06 October 1989

TOPIC -----

Is Mt. Xinu's K-Talk (formerly distributed by Kinetics) similar in function to MacTCP?

DISCUSSION -----

Although you can achieve similar results from MacTCP and K-Talk, there are some differences that you should be aware of. MacTCP is software installed on individual Macintoshes while K-Talk is software installed on a UNIX host. MacTCP provides TCP/IP connections for a Macintosh while K-Talk provides AppleTalk connections for a UNIX host.

At the point the packets reach the host machine running K-Talk, there is no need for a translation to TCP/IP. The K-Talk package, running on the UNIX host, translates the AppleTalk messages directly into UNIX file system calls without any intermediate steps.

## Ethernet/LocalTalk: TCP/IP Packets and GatorBox

Revised: 8/21/89  
Security: Everyone

Ethernet/LocalTalk: TCP/IP Packets and GatorBox

=====

This article last reviewed: 20 July 1989

TOPIC -----

The GatorBox is an Ethernet/LocalTalk bridge with NFS-to-AFP conversion. NFS runs over TCP/IP. AFP is an AppleTalk protocol. One would assume that the GatorBox takes NFS data in TCP/IP packets and converts them into AppleTalk packets with AFP suitable for AppleShare-style access via the Chooser. One also would assume that no TCP/IP is ever sent on to the LocalTalk side, and no AppleTalk on the Ethernet side, in this environment. Is this true?

DISCUSSION -----

On the LocalTalk side, the TCP/IP packets are encapsulated within AppleTalk packets by the router (the GatorBox) and shipped to the Macintosh. The Macintosh then interprets the TCP/IP "data" and does the necessary operations. In the environment specified, it is likely that no AppleTalk packets are being sent to the Ethernet, unless you are also using the GatorBox as an AppleTalk router.

## MacTCP: TCP/IP Encapsulation and DDP-IP Functionality

Revised: 8/21/89  
Security: Everyone

MacTCP: TCP/IP Encapsulation and DDP-IP Functionality

=====

This article last reviewed: 20 July 1989

TOPIC -----

Regarding DDP-IP functionality, is it true that MacTCP can send TCP/IP data embedded in AppleTalk packets (necessitating use of the DDP-IP gateway)? Can MacTCP direct TCP/IP packets directly on to an Ethernet (without a DDP-IP gateway)? Can K-Talk do this?

DISCUSSION -----

Yes, this is a fair representation of the functionality provided by MacTCP. When you are on a LocalTalk-based network, the TCP/IP packets are encapsulated within AppleTalk packets. When you are on an Ethernet, MacTCP uses TCP/IP directly without the encapsulation.

K-Talk does not provide quite the same capability. The best way to understand K-Talk is that it is software that resides on a UNIX host and provides AppleTalk services for AppleTalk clients (usually Macintoshes).

## Apple EtherTalk Card: 802.3 Implementation Described (8/94)

Revised: 8/31/94  
Security: Everyone

Apple EtherTalk Card: 802.3 Implementation Described (8/94)

=====

Article Created: 20 July 1989  
Article Reviewed/Updated: 31 August 1994

TOPIC -----

This article discusses Apple's implementation of 802.3.

DISCUSSION -----

Apple's implementation of 802.3 on the EtherTalk card is compliant with the 802.3 version 1 standard without any deviation. That is, Apple does not buffer its packets.

Apple uses the National Semiconductor 802.3 chip set consisting of a DP 8390 Network Interface Controller, DP 8391 Serial Network Interface, and the DP 8392 Coaxial Transceiver Interface. Buffering is handled in the DP 8390.

Apple's implementation should not raise any technical concerns with regard to bridging Ethernet segments, because Ethernet is a separate LAN specification from the 802.3 standard. Our Ethernet standard is compliant with the Digital/Intel/Xerox specification for an Ethernet local area network.

## Macintosh-to-AT&T 6544/IBM 3174 Controllers Connectivity

Revised: 8/21/89  
Security: Everyone

Macintosh-to-AT&T 6544/IBM 3174 Controllers Connectivity

=====

This article last reviewed: 20 July 1989

TOPIC -----

A customer has AT&T 6544 controllers. They are using IBM PCs (with Attachmate cards) to connect to the controllers to get to the mainframes. (The customer says that the wiring is twisted-pair.)

Is there a similar card available for a Macintosh II? Do you have any other suggestions on how to connect the Macintosh to the 6544 controller?

DISCUSSION -----

The AT&T 6544 controllers are clones of the IBM 3174 controllers with AT&T-added functions for twisted-pair terminal connections and support. For all practical purposes, your customer's configuration can be approached as a connection to an IBM 3174.

This can be done through an AppleLine or other third-party product for 3174 support (like an Avatar or DCA 3270 Coax Card) and terminal emulation software (like MacTerminal and 3270 FT from Apple or other third-party products). There are a number of such products, and some are listed in Tech Info Library.

While coax connections to the 6544 controller are possible, you can also connect to the twisted-pair RJ-11 connectors. A Balun is needed at the male end of a coax connector, for converting the signal levels to that of RJ-11 wiring. The Balun is similar to that found on the AppleLine product. Baluns are listed in most data communications trade catalogs, like the Black Box Catalog.

For more details, search the Tech Info Library under "Black Box Corp".

## AppleShare Print Server: Printing Problems Can Be Bad Net

Revised: 8/21/89  
Security: Everyone

AppleShare Print Server: Printing Problems Can Be Bad Net

=====

This article last reviewed: 20 July 1989

TOPIC -----

Apple Tech Comm has received a number problem reports recently concerning to AppleShare Print Server 2.0. The problem is "double printing" a print job or not printing all pages of a long print job (more than 10 pages) and restarting the print job. Here are two examples:

### Example #1

-----

If the spooler is chosen, the job is accepted and starts to spool to the printer. If the job is less than 10 pages, the print process completes with no problems. If the print job is greater than 10 pages, the print spools to the printer and stops at about page 6, and the print job repeats (from page 1). Our guess is that the LaserWriter times out and the print spooler restarts the job.

### Example #2

-----

AppleShare Print Server seems to have a problem. When a single-page document is sent to print with multiple copies, it seems to double the print request. That is, request 25 copies, receive 50 copies.

There is no indication in the print queue that two jobs are being printed, nor is there any mention of it in the print log. The problem occurs when printing from several Macintoshes so I know it is not the software on one particular Macintosh that is at fault.

DISCUSSION -----

It sounds as if the networks involved in these cases are poorly terminated. Poor termination can result in LaserWriters timing out. When connected to the print server, timing out prevents the print job from being closed out. Because the print server thinks the job failed before completion, it resends the entire

job, which results in double printing. Apple Tech Comm has experienced the same problem and eliminated it by cleaning the network connections.

## Apple IIGS: How To Prevent Control Panel Access

Revised: 10/18/91  
Security: Everyone

Apple IIGS: How To Prevent Control Panel Access

=====

This article last reviewed: 20 July 1989

TOPIC -----

Is there a way to lock the Control Panel on an Apple IIGS? If the Control Panel cannot be locked, is there a way to write an INIT to reset the PRAM to a predetermined setting?

DISCUSSION -----

The disposition of this problem depends on whether you have a pre-1MB Apple IIGS computer or a 1MB Apple IIGS computer:

Pre-1MB Apple IIGS Computer

-----

For older (pre-1MB Apple IIGS computers) you can, under ProDOS 16 and GS/OS, intercept the interrupt created by the Control Panel access keystroke. For these computers, you need to write an interrupt handler that accepts the Control Panel interrupt and disposes of it.

Startup programs, or INITs, are discussed in "Apple IIGS ProDOS 16 Reference" (ISBN 0-201-17754-4), published by Addison-Wesley. Pages 52 through 57 deal with the issues of boot initialization and the SYSTEM.SETUP subdirectory. Both issues are of importance to the creation of startup programs.

Interrupts and interrupt handlers are discussed in several places throughout the book. Use the index to review the issues connected with interrupts.

One shortcoming when using a startup program with ProDOS 16 or GS/OS concerns ProDOS 8 applications. When a ProDOS 8 application is executed, ProDOS also is executed, and, in the process, the INITs of ProDOS 16 or GS/OS are not active until ProDOS 16 or GS/OS is executed again.

1MB Apple IIGS Computer  
-----

The newer 1MB Apple IIGS computer has a jumper at W1 that disables the Control Panel. W1 is a two-pin jumper located on the logic board near the power supply.

## AppleFax Modem: Problems Receiving Data from Another Fax

Revised: 8/21/89  
Security: Everyone

AppleFax Modem: Problems Receiving Data from Another Fax

=====

This article last reviewed: 20 July 1989

TOPIC -----

A user with an AppleFax Modem is having trouble receiving Faxes from another Fax machine (the Hitachi DEX 6000). He has the new ROMs and is running System 6.0.2 and AppleFax 1.2 software on a Macintosh II.

A Hitachi technical representative told him that our modem was responding with an "RTP", not the expected "MCF".

He says that when the DEX initiates the call, it waits a moment and then tells him there was an error in communicating. On the Macintosh side, the AppleFax Modem answers the call and seems to be receiving the Fax, but when he prints it, he just gets garbage.

DISCUSSION -----

The "RTP" response sent by the AppleFax Modem is a request for retraining. The modem sends this request when the data sent by the calling Fax machine is corrupted during transmission. Phone line noise is one of the most common causes. The "RTP" response is a valid response according to the T.30 specification (the standard for Fax machine communications).

The "MCF" response expected by the DEX 6000 is a message confirmation response. This response is sent if the AppleFax Modem receives clean data from the phone line.

It appears that the DEX 6000 is sending a packet of information that is being corrupted by the phone lines. In response to the corrupted data, the AppleFax Modem is sending a request for retraining, which seems to be ignored by the DEX 6000. The AppleFax Modem continues to wait for the retraining that it has requested. The DEX 6000 apparently does not understand the "RTP" message, considers it an invalid response, and returns an error code to the DEX user.

## LocalTalk PC: Background Printing on AppleShare Not Supported

Revised: 8/21/89  
Security: Everyone

LocalTalk PC: Background Printing on AppleShare Not Supported

=====

This article last reviewed: 20 July 1989

TOPIC -----

A user has an AppleShare File Server and an MS-DOS machine using a LocalTalk PC Card. If he prints a file on LocalTalk (not on the server) in the background and, at the same time, tries to copy a file from the server to the MS-DOS computer, it bombs. He can do these separately, but not at the same time. Can you explain?

DISCUSSION -----

We don't know how background printing is being attempted in this situation. The AppleShare PC or LocalTalk PC environment does not provide a method for background printing. If the customer is attempting the background operations via some MS-DOS utility, the customer is exploring an untested and unsupported environment.

For MS-DOS, the only solution Apple provides is print spooling, which is accomplished using the AppleShare Print Server. Background printing is not provided.

The difference is that print spooling is provided by a network-accessible device that can be used by several network users. Background printing is a process that takes place on an individual's workstation and is accessible by that workstation's user only.

This article last reviewed: 20 July 1989

TOPIC -----

This article discusses APPC support in particular versions of VTAM and NCP.

DISCUSSION -----

Native PU 2.1 support is provided in VTAM Version 3 Release 2, NCP Version 4 Release 3, and NCP Version 5 Release 2.

One can, however, establish APPC connectivity under earlier releases of both products using a PU type 2 definition with many restrictions on the types of configurations supported.

These restrictions are:

- 1) Using a PU type 2 definition, the APPC node is relegated to the role of a SECONDARY logical unit. The APPC node defined as a PU type 2 CANNOT be a primary or negotiate roles.
- 2) The APPC node defined with a PU type 2 definition can have only ONE session with an application in the same subarea network. Parallel sessions and multiple sessions are NOT supported with a PU type 2 definition.

Therefore, you can run a MacAPPC node defined as a PU type 2 with earlier releases of VTAM and NCP with SINGLE SESSION, SECONDARY logical unit support only.

Please note that this restriction is NOT unique to MacAPPC only. All PU type 2.1 products (including System 3X and the IBM PC) share the same restrictions on sessions and logical unit roles in the VTAM/NCP environment.

Apple IIGS: Power Specifications and Discussion

=====

This article last reviewed: 21 July 1989

TOPIC -----

What is the milliampere output on the Apple IIGS? Is an overload possible? A customer has an Apple IIGS with all slots filled, and he cannot use his internal 2400-baud modem without disconnecting a card.

DISCUSSION -----

The following is a compendium of information from four different manuals and four engineers, with some common sense thrown in.

All DC outputs are regulated at the same time and their voltages will, to some extent, reflect unequal loadings. For example, if the +5V is loaded very heavily, then all other supply voltages will rise slightly. Conversely, if the +5V is lightly loaded, and the +12V is heavily loaded, both it and all other supplies will sag slightly.

Nominal current load ratio is:

+12V is 1/2 the +5V  
-5V is 1/10 the +5V  
-12V is 1/10 the +5V

The current capacities for the Apple IIGS power supply are:

| Power Supply | Max. Current Available |
|--------------|------------------------|
| -----        | -----                  |
| +12V         | 1.5A                   |
| +5V          | 4.0A                   |
| -12V         | 250 mA                 |
| -5V          | 250 mA                 |

This information was obtained from the label on the bottom of the power

supply.

The primary reasons for the stated limitations on the various supply voltages:

- 1) To ensure that the current capabilities of the traces and connectors are not exceeded.
- 2) To ensure nominal system loading.
- 3) To allow for memory card and its effects on the supply.
- 4) To ensure compatibility with existing cards.

It is a misconception that the current draw on any given supply on any given slot should be 1/7th the total current available. If there is 500 mA available on the +5V line, this means that the total current draw per slot should not exceed the stated maximum. One-seventh of 500 mA is 71.43 mA, which would almost demand the use of CMOS on all boards, but this is not the case. Some of Apple's interface cards exceed 71 mA.

#### Points To Ponder

- 
- 1) Tech Comm doesn't know of a test that would indicate a maximum current drain from each supply. As you can see from the earlier paragraph, the loading ratio plays a part in how the system reacts under load.
  - 2) Misconception as stated above. As long as the loading ratios are close to the stated ratio, higher supply loading might be possible without degradation.

#### Added Concerns

- 
- 1) The power supply capabilities are from the label on the bottom of the supply. These specifications were designed into, and marked on, the power supply by the manufacturer.
  - 2) The specified currents should not exceed the capabilities of the traces and connectors. If the customer is experiencing failures, it may be due to improper loading ratios and not current limitations. There is nothing physically added to the logic board to limit any current supplied to an interface card.

Our only concern, in this instance, is the loading ratio and the imbalance in the current drawn from the +12V and the +5V supplies. They are drawing almost three times the current from the +12V as the +5V. The best thing to do is to find a way to balance the load to match recommended the load ratio.

## LaserWriter Plus: 3.0 ROM, PostScript 47 Upgrade Available

Revised: 8/21/89  
Security: Everyone

LaserWriter Plus: 3.0 ROM, PostScript 47 Upgrade Available

=====

This article last reviewed: 21 July 1989

TOPIC -----

Is there a version 3.0 ROM for the LaserWriter Plus?

DISCUSSION -----

Yes, version 3.0 of the LaserWriter Plus ROMs contains version 47 of PostScript. To determine if a LaserWriter Plus has 3.0 ROMs, look on the test page at the line graph. The version number of the ROMs is at the bottom left corner of the chart.

If a LaserWriter or LaserWriter Plus does not have version 3.0 ROMs (PostScript version 47), you can upgrade the printers with the LaserWriter Plus Kit (M0191).

## Macintosh II Video Card: Problem Recognizing Other Video Cards

Revised: 8/21/89  
Security: Everyone

Macintosh II Video Card: Problem Recognizing Other Video Cards

=====

This article last reviewed: 21 July 1989

TOPIC -----

I have a Macintosh II 8-Bit Video Card and one Macintosh II Portrait Display Video Card in a Macintosh IICx. I've transported the Macintosh back and forth between two locations, one with an RGB monitor and the other with a Portrait Display monitor.

If the Portrait Display monitor is not connected, the Control Panel has no monitor selection and the Macintosh transfers all open windows and startup information (menu bar) to the RGB monitor. (This must be a new feature of the Portrait Display board only.) When I connect the Portrait Display and no RGB monitor, all of the information is output to the RGB card, and I cannot revert via the Control Panel.

It seems that only the Portrait Display Video Card senses if a monitor is connected. Can I make the RGB monitor disappear in the same way as the Portrait Display without pulling the card each time I transfer the Macintosh (my current strategy)?

Is this a new feature and will all new monitor boards have it?

DISCUSSION -----

Yes, this is a new feature that has been included in the Macintosh II Portrait Display Video Card and the Two-Page Monochrome Monitor Video Card. This feature will most likely be included in all of our future video cards.

There is no way to modify the Macintosh II 1-Bit Video Card, 4-Bit Video Card, or 8-Bit Video Card to behave in this manner.

## Macintosh: Performance in High-RFI Environments

Revised: 6/1/92  
Security: Everyone

Macintosh: Performance in High-RFI Environments

=====  
Article Created: 21 August 1989  
Article Last Reviewed: 27 May 1992  
Article Last Updated:

TOPIC -----

A user wants to put a Macintosh within three meters of medical equipment that generates sound waves up to 27.12 MHz. Can a Macintosh and an peripheral, like an ImageWriter or LaserWriter, work under these conditions without malfunctioning within a specified period?

The device is a CURAPULS 419; it generates HF signals as follows:

Generator frequency: 27.12 MHz  
Intensity (continuous): HF max 400W  
                          (pulsing): HF max 1000W  
Pulse rate: about 400 microseconds  
Pulse modulation: adjustable in 10 steps from 15-200 Hz

DISCUSSION -----

The frequency and wattage of the CURAPULS are not unlike that of high-frequency radio waves output by ham radios. Ham radio high-frequency waves are approximately 15 meters peak-to-peak at 21 MHz, or 10 meters at 28 MHz; whereas, the CURAPULS is 12 meters peak-to-peak at 27 MHz (27.12 MHz). Typical ham radio power output is 2,000 watts PEP (peak envelope power) and 1,000 watts DC (direct current), while the CARAPULS's appears to be 1,000 watts PEP and 400 watts DC.

Many ham operators are also computer enthusiasts and successfully use both electronic devices simultaneously. The key to the CURAPULS's impact on the Macintosh is how the radio waves are radiated. That is, will waves radiate from a roof antenna, or (because it is a medical instrument) contained within a shielded space or focused wand? If the waves are directly focused at the Macintosh with a high volts-per-meter intensity, you may have

difficulties.

Less hazardous symptoms of the high-frequency waves include distortion of the screen. Potentially more damaging symptoms include interference with reading and writing to disk drives.

Good shielding and grounding of the Macintosh and peripherals will reduce the effects of any symptoms. For instance, Macintoshes with internal drives are less susceptible to radio interference than external drives. Internal hard disks are less susceptible than external hard disks, which tend to have poorer shielding. External devices also have their own power cords, thereby making for a greater chance of ground loop interference.

Because Macintoshes aren't tested for susceptibility to external RFI, we cannot definitively state the amount of interference a Macintosh tolerates before problems may occur. Given the number of ham radio operators using computers near their antennas, and the similarity of the ham radio waves and the CURAPULS radio waves, it is not likely that there will be any major problems using the Macintosh while using the CURAPULS. However, be cautious; experiment with the location of the equipment using nonessential data. Such experiments might include a high number of read/write cycles to disks, followed by verification of data integrity.

## A/UX: CD-ROM Installation Issue

Revised: 9/29/92  
Security: Everyone

A/UX: CD-ROM Installation Issue

Article Created: 11 March 1991

### Article Change History

-----  
08/31/92 - REVIEWED  
• For technical accuracy.

### TOPIC -----

The README file on the A/UX CD-ROM installation floppy disc explains how to create space in the root file system. It says to remove the hard disk images of the manual pages and use the usr/catman files on the CD-ROM-based root&usr file system.

The last step is supposed to create a symbolic link, but the command contains an error that links the two catman directories together rather than symbolically providing the a\_man and u\_man files to the root file system.

The command as stated in README file:

```
ln -s /mnt/usr/catman /usr/catman
```

should be:

```
ln -s /mnt/usr/catman/* /usr/catman
```

Because of the permanent nature of the recommended changes, I strongly believe that the instructions should have the user create a dedicated mount point rather than using the /mnt mount point.

I believe that all Macintosh CD-ROMs should be mastered with the desktop icon closed as they are mounted. The A/UX 1.1 CD-ROM violates that common courtesy, and I hope the next version fixes that issue.

DISCUSSION -----

Yes, you're right. It must use "ln -s /mnt/usr/catman/\* /usr/catman" or the "man" will fail.

According to the previous remove commands in the README instruction, after finishing the 'rm -r /usr/catman/a\_man' and the 'rm -r /usr/catman/u\_man', the /usr/catman still remains a directory. Anything symbolically linked to the EXISTING directory will be created under that directory. Under this circumstance, the command:

```
ln -s /mnt/usr/catman /usr/catman
```

creates a symbolic link named "catman" under the /usr/catman directory.

Another comment on the 'ln -s' command: if the 'usr/catman' does not exist before using 'ln -s ...', the "/usr/catman" is created as a symbolic link to the /mnt/usr/catman directory.

## TCP/IP Packets: How AppleTalk Encapsulation Works (11/94)

Revised: 11/21/94  
Security: Everyone

TCP/IP Packets: How AppleTalk Encapsulation Works (11/94)

=====

Article Created: 21 June 1989  
Article Reviewed/Updated: 21 November 1994

TOPIC -----

TCP/IP packets are encapsulated in an AppleTalk packet for transmission over an AppleTalk network (for example, LocalTalk). When a router ships this encapsulated packet to the recipient Macintosh, how does the Macintosh know how to strip off the TCP/IP packet surrounding the data?

The Macintosh must know how to strip off AppleTalk packet information to get at the data, but what happens to the TCP/IP packet stored within that? If something, like MacTCP, is installed, this could take care of it. However, how does the GatorBox manage this, because the Macintosh can use NFS servers as AFP servers with no additional software other than the AppleShare workstation drivers installed?

DISCUSSION -----

As you stated, when the Macintosh receives TCP/IP packets encapsulated within AppleTalk packets, two steps are taken. The first is the stripping of the AppleTalk information and the passing of the enclosed data to the appropriate communications application or driver.

The second step is the interpretation of the TCP/IP packets by the receiving program. If you are using MacTCP, it handles the TCP/IP information in the same way that the AppleTalk drivers handle the AppleTalk information. If you are using an application that is not using MacTCP, like NCSA Telnet, then the application is responsible for providing the same functionality as that provided by MacTCP.

A GatorBox or similar device acts as a higher-level gateway. It translates NFS (Network File System) protocols into AFP (AppleTalk Filing Protocol) and presents it to a Macintosh. The Macintosh "sees" an AppleShare server and sends AFP requests to that server. These AFP requests are translated into NFS requests by the GatorBox software and are then sent to the host.

## AppleTalk: FastPath & GatorBox are Protocol Converter & Router

Revised: 8/21/89  
Security: Everyone

AppleTalk: FastPath & GatorBox are Protocol Converter & Router

=====

This article last reviewed: 21 June 1989

TOPIC -----

Is it true that a box, like the GatorBox and FastPath, can act in two modes, both operating at the same time if necessary?

DISCUSSION -----

It is true that a FastPath (and a GatorBox) can be both a protocol converter and an AppleTalk router.

These modes are as a simple router and as a gateway. As a simple router, it takes AppleTalk packets from one physical network (like LocalTalk) and routes them to another physical network (like EtherTalk). As a gateway, it takes data from a TCP/IP network and converts it to AppleTalk protocols (encapsulating the TCP/IP packet in an AppleTalk packet) at the same time as sending from one physical network to another in the same manner as the router aspect.

A vocabulary note: A gateway performs protocol conversion, like AppleTalk to TCP/IP. A bridge connects two physical networks as one logical network. In AppleTalk terms, this would mean that both physical networks would have the same network number. A router connects two physical networks and maintains them as separate logical networks. In AppleTalk terms, this means that each network has different network numbers although they may or may not be in the same zone.

## Apple IIGS: Error 911 Is Too Many Sync Errors on ADB

Revised: 8/21/89  
Security: Everyone

Apple IIGS: Error 911 Is Too Many Sync Errors on ADB

=====

This article last reviewed: 21 July 1989

TOPIC -----

On an Apple IIGS with the 0077B ROM installed using GS/OS, I occasionally run into a Fatal System Error ID=911. In one case, it happens when the I switch from MS-DOS (Applied Engineering, PC Transporter) to ProDOS. In another case, it occurs after shutting down the Control Panel. Running the Cortland Diagnostics does not locate the problem. Error ID=911 has to do with the Apple Desktop Bus.

DISCUSSION -----

ID=911 means that too many sync errors occurred on the Desktop Bus. This problem has been identified but not fixed in currently produced logic boards. It has, however, been targeted for inclusion in future revisions.

## LaserWriter IINTX: Attached Hard Disk Can Slow Printing Speed

Revised: 3/4/90  
Security: Everyone

LaserWriter IINTX: Attached Hard Disk Can Slow Printing Speed

=====

This article last reviewed: 21 July 1989

TOPIC -----

I have heard from Adobe Technical Support that adding a hard disk to a LaserWriter IINTX does NOT increase printing speed. Do we have any general or specific speed comparisons on the hard disk and LaserWriter IINTX configuration?

DISCUSSION -----

Technically, adding a hard disk to a LaserWriter IINTX does slow down printing. This is because when searching the font list (ROM and disk-based), the system searches the entire list (even though the font may be in ROM) and sends one packet for each and every font. Further, the search continues through the list even after the desired font is found. Engineering is aware of this and is planning to fix it in a future revision.

When printing using a font not contained in the LaserWriter II ROM, the fastest printing is achieved once the font is held in the LaserWriter II RAM. Fonts downloaded from the System Folder result in the slowest printing. Printing with fonts stored on the hard disk falls somewhere in between.

Depending on the context of your discussions with Adobe Technical Support, their statements could be accurate. Most of the information we gathered in previous discussions on this subject came from Adobe engineers.

AppleFax Modem: Power Supply Pinouts

=====

This article last reviewed: 21 July 1989

TOPIC -----

I need the pinouts on the back of the AppleFax Modem for the power supply cable.

DISCUSSION -----

The pin assignments in the cable:

| Pin | Function     |
|-----|--------------|
| 1   | +12 volts    |
| 2   | Earth Ground |
| 3   | Return       |
| 4   | +12 volts    |
| 5   | Return       |
| 6   | -12 volts    |
| 7   | +5 volts     |

The end view of the pin layout in the cable's connector looks like:

```

  7  x      x  6
3  x      x  1
  5  x      x  4
      x
      2
```

## Intermedia: General Information

Revised: 9/14/92  
Security: Everyone

Intermedia: General Information

Article Created: 21 August 1989

### Article Change History

08/31/92 - REVIEWED

- For technical accuracy

Swami

### TOPIC -----

This article describes the Intermedia software product.

### DISCUSSION -----

Intermedia, developed by Brown University's Institute for Research in Information and Scholarship (IRIS), in conjunction with Apple Computer, is a tool that lets users build "webs" of information consisting of text, graphics, timelines and scanned images. Intermedia runs under A/UX, using the Macintosh Toolbox interface. Documents are shared using NFS (Network File System).

Intermedia consists of four integrated applications:

- InterWord, a word processing program
- InterDraw, a structured graphics editor that with InterPix, a scanned image viewer, lets users create and display diagrams and bitmap images
- InterPix, a scanned image viewer
- InterVal, a timeline editor that helps manage temporal events by displaying them in chronological order. It has the capability to link together materials created by those applications into an exploratory web of ideas.

The IRIS Intermedia system has two parts. First is the IRIS Intermedia

Server. It runs on a Macintosh system connected to a network and manages both the document file system and a network-accessible database. The database contains the information about interdocument links and the Intermedia Client.

Intermedia Client runs on individual workstations and includes the four applications--InterWord, InterDraw, InterPix, and InterVal. The IRIS InterLex Server is an optional Intermedia component, providing network-wide access to a full version of Houghton Mifflin's American Heritage Dictionary from any of the other applications.

In a sample IRIS Intermedia web, "Exploring the Moon," students interested in lunar exploration can browse through a collection of materials about the Apollo Missions, including details of the scientific objectives and goals of each mission.

The IRIS Intermedia system is available through APDA for or through IRIS. When purchased through APDA, customers in the U. S. are eligible for up to two hours of free A/UX hotline support for the first 90 days. The package includes the Intermedia Server and Intermedia Client software, tutorials, and documentation. Available directly from IRIS at Brown are "Exploring the Moon" and the IRIS InterLex Server.

In a stand-alone installation, Intermedia requires one dedicated Macintosh II, IIx, or IICx system running A/UX 1.1, with at least 4 megabytes of RAM to act as both the server and client. In a networked installation, Intermedia requires one dedicated Macintosh II, IIx or IICx running A/UX 1.1, with at least 4 megabytes of RAM to act as the server and any number of similarly-configured Macintosh systems to run as clients. An additional 40 to 80 megabyte hard disk is recommended for storing documents and data of any significant size.

For more details, search the Tech Info Library under "APDA" and "IRIS".

## IBM 319X: Terminal Product Line Overview

Revised: 10/4/89  
Security: Everyone

IBM 319X: Terminal Product Line Overview

=====

This article last reviewed: 26 May 1989

Throughout 1987 and 1988, IBM introduced a number of new display terminals. These new devices are functional equivalents to the 3X7X coaxial and 525X twin-axial devices. In June, 1988, IBM added to it's line of ASCII Asynchronous terminals.

There are some significant new features with the product line over the older 327X and 317X devices. Enhancements include color support on all models (previously restricted to mod 2 and 3 devices) and DFT support with 3194's.

The new graphics workstation supports a mouse. The recently discontinued light pen feature is back on selected mod 2 and 3 devices.

The new devices reduce the required "footprint" of 328X devices by about 50%. Newer electronics speed the processing of the displays, making the devices slightly faster than earlier products. These redesigns allow for printer buffering, pass through, and some other features (on selected models) which have been popular on 327X-compatible devices and ASCII terminals offered by third parties for many years.

IBM claims to have reduced the number of keyboard options from over 200 to three basic models. This is not quite true, as data entry and APL keyboards are still available. The new keyboards are waterproof. 319X series devices feature "auto dim screen savers" to reduce the amount of screen burn-in and increase CRT life

The 319X line (except the 3193) also features built-in baluns. Baluns are used with a special IBM cable that has a keyed coaxial connector at one end and an RJ11 at the other. The following is a summary of the devices and features now offered by IBM.

The older 327X and 317X devices are no longer on IBM's price list. However, the 3290 gas-plasma display is still available.

The 319X 3270 replacements will operate on 3274, 3174 controllers, and 937X direct coaxial attachments except as noted in the special features section.

The 3196 and 3197 operate on System 3X or AS/400 direct attached twin-ax or the 5251-12 (with restrictions) and 5294 remote controllers, except as noted in the special features section.

## IBM 3151 ASCII Display Station Family

Revised: 10/4/89  
Security: Everyone

IBM 3151 ASCII Display Station Family

=====

This article last reviewed: 26 May 1989

This product line was introduced in June, 1988. These ASCII displays augment the already existing line of 316X ASCII displays. The model 310 and 410 feature plug in cartridges to implement optional terminal emulators and features, such as RS422A. 3708 enhancement mode allows pass through printing as a local or system printer to a display attached ASCII printer by seizing two LU's from the 3708 remote protocol converter. Three models are offered. The following table summarizes the features of each model.

|                         | 3151-101<br>-----                                                                       | 3151-310<br>-----                                                                       | 3151-410<br>-----                 |

## IBM 3191 Displays

Revised: 10/4/89  
Security: Everyone

IBM 3191 Displays

=====

This article last reviewed: 30 May 1989

The IBM 3191 displays are functional replacements to the 3178 and 3278 class of devices. There are seventeen different models. Here are some of the highlights:

### Displays and Phosphor for 3191 Displays

-----  
A series models feature 12-inch green phosphor screens and support mod 2 (24x80 with 1 status line) formats.

B series models feature 12-inch amber-gold phosphor screens and support mod 2 formats.

D series models have 14-inch green phosphor screens and support mod 2 and 3 (32x80 with 1 status line) formats.

E series models feature 14-inch amber-gold screens and support mod 2 and 3 formats.

L series displays have green phosphor 14-inch screens and support mod 2 and 3 formats.

3191's do not support graphics.

### Keyboards

-----  
The three standard keyboards are offered. The 102 key keyboard is a PC keyboard with 24 function keys. The 104 key is a full, typewriter keyboard with 24 function keys and no numeric pad. The 122 is a full, typewriter keyboard with 24 function keys and a numeric pad. A fourth keyboard (Data Entry configuration based on a 104 key keyboard) is offered on the A40 and B40 display stations. Each keyboard is bundled with a display, so the second digit of the model number indicates which keyboard is in the bundle. The keyboard is waterproof and can be modified in setup mode. The keycaps

can be removed and replaced for specific applications.

#### Special Features

-----  
The L series features a light pen. The D, E, and L series devices support an async "personal printer port" for local screen prints directly from the display. 3191's have internal baluns and use a special IBM cable with a special, keyed connector with a coaxial attachment at one end and an RJ11 on the other.

#### Pricing

-----  
The 3191 series devices are priced as follows (list price as of 8/17/88)  
One- and three-year warranties are offered with all 3191's.

|          | 1 yr warr | 3 yr warr |
|----------|-----------|-----------|
| A series | \$1235    | \$1355    |
| B series | \$1290    | \$1355    |
| D series | \$1490    | \$1595    |
| E series | \$1490    | \$1595    |
| L series | \$1880    | \$2160    |

Internal Balun special cable \$15.00

## IBM 3192 Displays

Revised: 10/4/89  
Security: Everyone

IBM 3192 Displays

=====

This article last reviewed: 30 May 1989

The IBM 3192 displays are functional replacements for the 3279 and 3179 series display stations. There are 19 different models. Here are some of the highlights:

### Displays and Phosphors

-----

The 3192 C series has 14-inch color screens and supports mod 2 and 3 formats. The C series does not support graphics.

The D series features 15-inch screens with green phosphor and is available in mod 2, 3, 4 (43x80 with one status line), and 5 (27x132 and one status line) formats. The D series does not support graphics.

The F series features 14-inch color screens and supports mod 2, 3, 4, and 5 formats. The F series does not support graphics.

The G series features 14-inch color screens and is available in mod 2 and 3 formats. The G series supports graphics and replaces the 3279-S3G, 3179-G10, and G20 graphics display stations. These devices require GDDM version 1 release 4 or GDDM version 2 and the Presentation Graphics Feature (PGF) on the mainframe to operate in graphics mode.

The L series features 14-inch color screens and supports mod 2 and 3 formats. The L series features a light pen. The L series does not support graphics.

The W series features 15-inch screens with Black characters on a White background. This feature can be reversed (for IBM purists). The W series supports mod 2, 3, 4, and 5 formats. The W series does not support graphics.

### Keyboards

-----

Three, standard keyboards are offered. The 102 key keyboard is a PC keyboard with 24 function keys. The 104 key is a full typewriter keyboard with 24 function keys and no numeric pad. The 122 is a full typewriter keyboard with 24 function keys and a numeric pad. A fourth APL keyboard is offered for two models in the G series in 104 and 122 key formats. The keyboard is waterproof and can be modified in setup mode. The keycaps can be removed and replaced for specific applications. Each keyboard is bundled with a display. The second digit of the model number indicates which keyboard is in the bundle.

#### Special Features

-----  
All 3192 displays support the printer port feature. All 3192 C and L series devices support the Record/Play/Pause feature. This means the user can store up to 1500 characters and "play back" or modify these characters. The 3192 C and L series also support the "screen trim" feature. This lets you use the cursor to "box in" what will be printed on your personal printer. The 3192 C series is functionally compatible with the 3279 S2A, S2B, S2X, and the 3179-1. The G series supports the IBM Color Jetprinter (3852 model 2) off the printer port. The G series also supports the IBM 5277 Mouse, the IBM 6180-2, 6184, 7371, and 7372 Color Plotters via the IBM 3979 Expansion Unit. The G series displays cannot be attached to 3174 81R or 82R remote controllers.

3192s have internal baluns and use a special IBM cable \* with a special keyed connector with a coaxial attachment at one end and an RJ11 on the other.

#### Pricing

-----  
The 3192 series devices are priced as follows (list price as of 8/17/88)  
One and three year warranties are offered with all 3192's.

|          | 1 year warr | 3 year warr |
|----------|-------------|-------------|
| C series | \$1985      | \$2140      |
| D series | \$1880      | \$1985      |
| F series | \$2195      | \$2350      |
| G series | \$2925      | \$3135      |
| L series | \$2405      | \$2745      |
| W series | \$2090      | \$2245      |

## IBM 3193 Displays

Revised: 10/4/89  
Security: Everyone

IBM 3193 Displays

=====

This article last reviewed: 30 May 1989

The 3193's are "image processing" devices. IBM "image processing" devices use predefined (fixed) graphics images. These images are treated like character sets and are called "graphics symbol sets." The 3193 product line is used on 370-architecture systems with specialized applications.

### Displays and Phosphors

-----

The 3193 features black on white displays with 15-inch screens. They support mod 2, 3, and 4 formats plus a 48X80 image-processing format. The 3193 screen is designed as a full-page display.

### Keyboards

-----

The 3193 supports the 102 and 122 key keyboards. The keyboard is waterproof, and can be modified in setup mode. The keycaps can be removed and replaced for specific applications.

### Special Features

-----

The 3193 does not support the printer port. The 3193's can support attachment of IBM 3117 and 3118 scanners.

### Pricing

-----

The 3193 series devices are priced as follows (list price as of 8/17/88) A one-year warranty is offered with the 3193.

Model 010 \$2610

Model 020 \$2610

## IBM 3194 Advanced Function Displays

Revised: 10/4/89  
Security: Everyone

IBM 3194 "Advanced Function" Displays

=====

This article last reviewed: 30 May 1989

The 3194 is the most powerful of the nine models in the new display station product line. All 3194 display stations are capable of running in CUT or DFT mode. This represents a significant enhancement to the IBM display-station, product line. In the past, DFT mode was restricted to the 3290 gas-plasma display.

The 3194 is almost a PC system with an 8 mhz 80186 microprocessor, 640K of memory and a 720KB 3.5 inch floppy disk drive as standard features. However, there are many incompatibilities between a 3194 and an MS/DOS or OS/2 system. Please read the "Special Features" section before jumping to any conclusions about this product. It's quite sophisticated, but it's not an IBM PC.

### Displays

-----

The C series features a 12-inch color screen and supports mod 2 and 3 formats. The C series does not support graphics.

The D series features 15-inch green phosphor screens and supports mod 2, 3, 4, and 5 formats. The D series does not support graphics.

The H series features 14-inch color screens and supports mod 2, 3, 4, and 5 formats. The H series does not support graphics.

### Keyboards

-----

The three standard keyboards are offered. The 102 key keyboard is a PC keyboard with 24 function keys. The 104 key is a full, typewriter keyboard with 24 function keys and no numeric pad. The 122 is a full, typewriter keyboard with 24 function keys and a numeric pad. The keyboard is waterproof and can be modified in setup mode. The keycaps can be removed and replaced for specific applications. Each keyboard is bundled with a display, so the second digit of the model number indicates which keyboard is

in the bundle.

#### Special Features

-----  
In addition to the standard 640K of memory, you can add a memory upgrade of an additional 192K. A 2MB 3.5 inch floppy drive is also available.

DFT support gives the user the capability of having five host sessions active at once. Four of these sessions can be 3270. With an optional async interface, one of these sessions can be with an ASCII/Async host. The Async feature uses VT100 terminal emulation. The device also supports two notepads and one local "utility session", used to customize the display, manage the diskettes, initiate file transfers, and do maintenance functions like traces, dumps, and patches. The 3194 does not do "windows" in the Macintosh sense, but instead toggles (using a "jump" key) from session to session and provides a "screen split" capability.

Another significant feature is the implementation of an open 3270 API interface on the 3194 products in DFT mode. This allows custom programming of the device allowing multiple host/multiple session capabilities transparent to the end user through application specific API programming (using IBM's HLLAPI). This lets the programmer create "composite" screens from multiple sessions to one or more host applications.

The API applications MUST be downloaded from the host. You cannot store these on the local floppy disk. Development of these custom applications can be done on an IBM PC with your favorite compiler using HLLAPI extensions. This program is then compiled on the PC and uploaded to the host, which distributes it to the devices. A "Device Function Modifier" package is used to develop applications on the 3194 (if you don't want to use a PC). The applications are uploaded to the host for distribution to target 3194's.

The disk drive also lets you use DFT implementations on remote controllers which do not support downline loading of microcode (like the 3174-81R or 82R).

The 3194's operating system has a restricted user "shell." The 3194 does not run MS-DOS programs. It is intended for use in accounts where some local intelligence (for custom API programming) is desirable, but PC implementations are not. This puts control of the device firmly in the hands of MIS management, rather than in those of the end user.

The disk drive format is incompatible with OS/2 and MS/DOS storage formats, so forget about reading a 3194 disk on an MS/DOS or OS/2 compatible disk drive.

The device supports file transfers to IBM IND\$FILE packages under MVS/TSO, VM/CMS, and CICS version 1 release 6 mod 1. You can use this file transfer capability to enhance the API programming and API functionality of the workstations. As the disk storage formats are incompatible with the MS/DOS or OS/2 product line, you cannot share this data with a MS/DOS or OS/2 compatible disk drive. The local Utility session capability lets the user

initiate file transfers with IND\$FILE mainframes. File transfers may also be initiated by a custom API program.

All 3194 displays support the printer-port feature. All 3194's support the Record/Play/Pause feature, through which the user can store up to 1500 characters and "play back" or modify these characters. 3194's have internal baluns and use a special IBM cable with a special keyed connector with a co-axial attachment at one end and an RJ11 on the other.

#### Pricing

-----

The 3194 series devices are priced as follows (list price as of 8/17/88)  
One-year warranties are offered with all 3194's.

|          |               |

## IBM 3196 and 3197 Displays

Revised: 10/4/89  
Security: Everyone

IBM 3196 and 3197 Displays

=====

This article last reviewed: 30 May 1989

The 3196 and 3197 displays are functional replacements for the 5251 and 5292 product line. These are twin-ax devices, intended for use on the System 3X and AS/400 product lines. There are four models in the 3196 line and seven models in the 3197 line. These devices do not display graphics.

### Displays and Phosphor

-----

The 3196 A series features 12-inch green phosphor screens, in 24x80 (with one status line) format. The 3196 B series features 12-inch amber-gold screens in the 24x80 (with one status line) format.

The 3197 C series features 14-inch color screens and supports 24x80 (with one status line) formats. The 3197 D series features 15-inch green phosphor screens and supports 24x80 (with one status line) and 27x132 (with one status line) formats. The 3197 W series features 15-inch black on white displays in 24x80 (with one status line) and 27x132 (with one status line) formats.

### Keyboards

-----

Both product lines support the 102 PC keyboard with 24 function keys and the 122 key keyboard with 24 function keys and a numeric pad. A data entry keyboard, based on the 122 key offering, is available on the 3197 D40. The keyboards are waterproof and have System 3X-oriented key caps.

### Special Features

-----

Both product lines support the Record/Play/Pause feature, through which the user to store up to 1500 characters and "play back" or modify these characters. The printer-port feature is available on the 3197 product line. The 3197 C series supports dual sessions, applications designed for the 5292 model 1 and 3179 model 2, and system printing through the printer port. All these workstations attach directly to a System 3X or AS/400. Remote attachment to a 5251-12 is supported only for 24x80 screen sizes. The

5251-12 does not support color. Remote attachment of 3196 models A20 and B20 are not supported on either remote controller. The remainder of the displays (including color) can attach to the 5294 remote controller.

#### Pricing

-----

The 3196 and 3197 series devices are priced as follows (list price as of 8/17/88)

|          | 1-yr warr | 3-yr warr |
|----------|-----------|-----------|
| A series | \$1270    | \$1355    |
| B series | \$1270    | \$1355    |
| C series | \$1895    | \$2140    |
| D series | \$1795    | \$1985    |
| W series | \$2090    | \$2245    |

## HyperCard: How To Find Character Number in a Field

Revised: 6/24/90  
Security: Everyone

HyperCard: How To Find Character Number in a Field

=====

This article last reviewed: 17 August 1989

TOPIC -----

How can I return the "number" of the first character of a line in a HyperCard field?

Since each TextEdit Record contains an array containing the number of the first character of the line, I'd like to access that information.

DISCUSSION -----

You can find the number of the first character of line x in a HyperCard field by using the following script:

```
if x = 1
then
  put 1 into charNum
else
  put (the length of line 1 to (x-1) of fld test) + 1 into charNum
end if
```

The only problem with the script is that HyperCard considers a line as a line only if it is terminated with a carriage return. Line endings that result from word-wrap in a field are not counted as lines.

For example, a field set to display eight characters wide is filled with 20,000 characters without a carriage return. The display shows approximately x lines, but HyperCard considers the field to only have one line.

Since HyperCard returns only a null-terminated string of characters as field contents, you cannot use an XCMD to retrieve the line-starts information.

## AppleShare Print Server: Extra Line Feeds on ImageWriter II

Revised: 12/14/92  
Security: Everyone

AppleShare Print Server: Extra Line Feeds on ImageWriter II

=====

Article Created: 17 August 1989

### Article Change History

-----

12/10/92 - UPDATED

- To include AppleShare 3.0.1 Print Server information.

### TOPIC -----

I'm printing to an ImageWriter II with AppleShare Print Server. With spooling and the sheetfeeder attached, I get additional line feeds at the top of the page. If I bypass spooling, it prints fine.

### DISCUSSION -----

With AppleShare Print Server versions 2.0 and 3.0, the print server supplied incorrect information to the client about the printer configuration. This caused the paper to advance before the start of the page and again at the end of the page.

AppleShare Print Server version 3.0.1 fixes the problem.

## HyperCard: Problem With Dial Command and Apple Personal Modems

Revised: 8/23/89  
Security: Everyone

HyperCard: Problem With Dial Command and Apple Personal Modems

=====

This article last reviewed: 17 August 1989

TOPIC -----

Where can I find the documentation for driving (play) telephone tones from HyperCard?

The application that I am working on requires talking to an audio response unit at a bank that automates bill paying. The remote machine talks using digitized audio requesting account code, password, and so on, expecting the user to type in appropriate responses from the telephone keypad. I want to automate this in HyperCard.

My Apple Personal Modem and the dial command appear to have limitations (perhaps just limited documentation) that prevent me from doing what's needed -- namely, to order the modem to dial a number with a ";" appended so that it remains off hook when a voice answers. Instead, the dial command appears to strip off this character.

Can the modem be used this way?

DISCUSSION -----

Certain Apple Personal Modems, those with a serial numbers beginning with a C621301 to C745577, do not work properly with the HyperDialer stack.

The problem exists because one of Apple's vendors incorrectly substituted 2.3-ohm resistors for 4.7-ohm resistors, which altered some characteristics of the modem. The resistors are surface-mount type, numbered R106-107, with the following numbers on the resistors: 4R7 (incorrect) or 2R3 (correct).

Try to dial using a modem outside the range specified above. If the problem is not present in that situation, the original modem can be fixed by any Apple service provider.

## AppleShare: Why Macintosh Can't Launch From Server

Revised: 10/4/89  
Security: Everyone

AppleShare: Why Macintosh Can't Launch From Server

=====

This article last reviewed: 17 August 1989

TOPIC -----

Why is it possible to boot from an AppleShare server with Apple IIGS, when it has never been possible to do that with the Macintosh?

DISCUSSION -----

The design goals for the Macintosh are different from the design goals for the Apple IIGS. The size of a System file on the Macintosh can easily get to be very large; thus, it would take a long time to launch a large System file from an AppleShare server.

Also, since the Apple IIGS was intended for different purposes, being able to launch from the server was considered vital. This is not the case with Macintosh.

Because of the size of a Macintosh System file versus the size of an Apple IIGS or Apple IIe System file, it would take too long to launch a Macintosh from an AppleShare server.

## AppleShare: AFP User Authentication Methods

Revised: 10/4/89  
Security: Everyone

AppleShare: AFP User Authentication Methods

=====

This article last reviewed: 17 August 1989

TOPIC -----

In a test I did using Peek over the AppleShare network, I was able to identify both my name and password. Why?

DISCUSSION -----

There are three defined user authentication methods available to AFP servers and workstations. The workstation indicates its choice of user authentication method (UAM) by giving the server a UAM string.

- 1) No user authentication: This method needs no specification. No user name or password information is required in the FPLLogin call. The corresponding UAM string is 'No User Authent'. An example of this would be to log on as a guest.
- 2) Cleartext password: This method uses the UAM string of 'Cleartxt Passwrđ'. The password is transmitted as clear text and is not encoded in any way. The User Info part of the FPLLogin call consists of the user name followed by the user's password.
- 3) Random number exchange: This method is best used when a network is not secure from eavesdropping. This method uses the UAM string of 'Randnum Exchange'. If this method is not supported by the AFP server, the workstation will use the Cleartext password UAM. This is the method used by Apple workstation software when accessing an AppleShare file server.

The Apple workstation software uses the FPGetSrvrInfo call to find out what UAMs the server supports. This is done to determine what password UAM should be used. A way to find out what password UAM is supported is to use the AppleShare Chooser item and select a server. Next to the password field you will see either '(Scrambled)' or '(Clear text)'. If you see

'(Clear text)', it means that the AFP server does not support the Random number exchange UAM.

## CD-ROM: Information on Different CD Formats

Revised: 8/23/89  
Security: Everyone

CD-ROM: Information on Different CD Formats

=====

Article Created: 17 August 1989  
Article Last Reviewed: 22 May 1992  
Article Last Updated:

TOPIC -----

This article contains a list of CD format acronyms and some explanation of their function.

DISCUSSION -----

A glossary of CD acronyms:

|           |                                        |
|-----------|----------------------------------------|
| CD+G      | Compact Disc plus Graphics             |
| CD+V      | Compact Disc plus Video                |
| CD+MIDI   | Compact Disc plus MIDI                 |
| CD+MIDI+G | Compact Disc plus MIDI plus Graphics   |
| CDI       | Compact Disc Interactive               |
| CD-DVI    | Compact Disc Digital Video Interactive |

The graphics of the "CD+G" format are simple computer-type graphic images.

The video of the "CD+V" format is an NTSC video signal, such as what is found on laser discs. This format allows the use of part of the CD for the video signal. This is used most often for music videos. A typical CD will include twenty minutes of music without video and a five-minute or less music video.

The MIDI of the "CD+MIDI" format is MIDI data stored on the CD for use with MIDI-controlled electronic instruments. This allows use of your own MIDI instruments as supplemental instruments to what is recorded on the CD. For example, should you want more bass on a particular song, connect a MIDI instrument with a bass sound to a CD player supporting CD+MIDI, assign the MIDI instrument to the proper channel, and adjust the level of the MIDI device to complement the song coming from the CD music tracks.

The "CD+MIDI+G" format combines the "+G" format and the "+MIDI" format on one disc. This format requires the chip sets for both the graphics decoding and the MIDI decoding.

"CDI" is very similar in many ways to the video disc/HyperCard presentations that have been shown. Generally, however, the computer information and the video information are both stored on the CD.

"CD-DVI" is also very similar at the presentation level to the video disc/HyperCard environment. However, the chip set for this environment is proprietary to Princeton University and Intel. The difference between DVI and CDI relates to the method of storing the video images. DVI digitizes and compresses the video frames prior to storage on the disc. During playback the video frames are decompressed by the chip set. CDI uses analog video for its video storage.

With the exception of the CD+V format, these formats have been proposed by one or maybe two organizations. The worldwide CD industry has not adopted these formats. Much discussion is taking place among both the hardware manufacturers and the software producers concerning how this diverse set of standards are going to be handled. There are several limited projects taking place within each of these CD formats; however, without worldwide industry support, some of these formats may fall by the wayside.

## AppleCD SC: Cannot Play CD+G, or Other Formats

Revised: 8/23/89  
Security: Everyone

AppleCD SC: Cannot Play CD+G, or Other Formats

=====

This article last reviewed: 17 August 1989

TOPIC -----

Can the AppleCD SC be modified to play in the CD+G format?

CD+G players have one laser (standard) that reads the music track and the graphics (G) track, then sends the signals to separate outputs.

The graphics are sent to an attached monitor. From what I have been told, any CD player can perform this task with proper circuitry.

Can the AppleCD SC be modified to play this format? Can the pinouts on the SCSI be tapped to read the video signal and displayed on a monitor device?

DISCUSSION -----

The key to achieving this is the "proper circuitry". This proper circuitry (a chip set somewhat like the audio chip set in the AppleCD SC) must tap the signal coming directly from the laser, not a downstream location such as the SCSI connector. The laser controller must also be aware of the need to scan the graphics tracks as well as audio tracks. Since the circuitry is needed simply to find the graphics tracks, the graphics information is NOT available within the AppleCD SC.

Adding the graphics mode to any CD player requires the initial design to allow that mode. Since the AppleCD SC was designed and manufactured prior to the CD+G format becoming a reality, adding this feature is not possible: a completely new design would be required to support the CD+G disc format.

The same situation faces support for CD+V, CD+MIDI, CD+MIDI+G, CDI, and CD-DVI; each different disc format requires supporting circuitry to decode the appropriate digital information recorded on the disc.

## AppleShare PC: NetBIOS Interrupt Problem

Revised: 8/23/89  
Security: Everyone

AppleShare PC: NetBIOS Interrupt Problem

=====

This article last reviewed: 10 August 1989

TOPIC -----

I am currently trying to run an IBM-XT as a gateway/router between the AppleTalk network and MS-DOS on Ethernet.

This is to support an electronic mail system for use in both the DOS and Apple environment.

The standard NetBIOS call is performed through INT 5Ch. When the Ungermann-Bass or Excelan network is started, this software interrupt is enabled as part of the standard Microsoft network software. AppleShare PC steals this interrupt away from the standard Microsoft NetBIOS.

This allows using the predefined network interface with AppleShare PC but does not allow it to coexist with the normal PC LAN software.

DISCUSSION -----

AppleShare PC uses the standard Microsoft redirector that communicates with other processes via interrupt 5C. If a process similar to AppleShare PC does not properly share this interrupt with the other processes trying to get access to the redirector, the symptoms you describe occur. AppleShare PC has been written to coexist with other "interrupt 5C friendly" programs.

Try running AppleShare PC as the last of your startup programs. It will try to maintain the interrupt for another process that isn't as "friendly" in the use of interrupt 5C. This often works, because AppleShare PC looks at the previously installed vectors for that interrupt; when it gets information not belonging to it, it passes it along the chain to whoever was there before it.

## Macintosh: Desktop Media & the Making of Pencil Test (1 of 2)

Revised: 8/23/89  
Security: Everyone

Macintosh: Desktop Media & the Making of Pencil Test (1 of 2)

=====

This article last reviewed: 18 August 1989

TOPIC -----

Companies who want to implement computer-generated video systems for their training and PR departments wonder whether to go with the Macintosh open, modular system or with an integrated system.

Some have seen non-Apple solutions that include a single, Amiga-based package with automated, three-dimensional, frame-by-frame generation of NTSC video sequences. The package also handles the problems of hiding window borders/title bars, genlocking, and so on.

Most have seen the "Pencil Test" video and feel that the quality of this video is acceptable, but they were told from one of the other vendors that Apple invested incredible resources into creating "Pencil Test" and that the process used for "Pencil Test" was very time-consuming and inefficient.

What was the exact process for the creation of "Pencil Test"? How many people worked for how long to produce the video?

DISCUSSION -----

There are advantages and disadvantages both to the totally integrated systems and the open modular systems. Totally integrated system's advantages include having hardware and software tied directly together and having one place to get support. Disadvantages include being locked into the one company's point of view about how to do things, working only with their tools, and, often, being locked into that company's software. An integrated solution on non-Macintosh systems is most likely pieced together from a variety of third-party products.

Open module systems offer one of the main advantages of Macintosh: integration. With the Macintosh consistency of user interface, different modules from different publishers have the familiar user interface. The best drawing program can be used with the best animation program while using the best video card.

There are standard graphics file formats that are used by animation applications. Also, graphic images can be copied and pasted among most Macintosh applications. For example, if a corporate logo is designed for publishing in Macintosh publishing programs, that logo can be brought into the Macintosh animation programs. The logo also can be used in programs for making 35mm slides or overhead transparencies. You don't need to redraw it or convert from one computer format to another.

Another advantage of having a modular system is the hardware. The current standard for graphics applications is 8 bits of data for each pixel or 256 colors at one time. Many hardware and software companies are now working on 32 bits of data for each pixel or more than 16,000,000 colors on screen at one time. In a modular environment, as technology progresses, the animation environment can progress by updating the portions that are necessary--not changing to something entirely different.

The basis of the MacroMind system is VideoWorks. VideoWorks II and Director has the ability to hide window borders, title bars, and menu bar. MacroMind has also worked with other graphics companies to establish a standard file format for the exchange of animated sequences. This format is called PICS.

Aegis offers Showcase F/X for doing animated titles.

Certain Macintosh video cards, designed for outputting to NTSC, correctly handle all the issues concerned with placing Macintosh graphics on video tape, like overscan and genlock. The AST video board, the Mass-Micro Color-Space II, ComputerFriends TV Producer, TrueVision NuVista cards with VIDI/O Box, and RasterOps ColorBoard 64NC all are boards that handle the proper placement of the graphic images for full-screen coverage and genlock.

There are other methods for moving Macintosh graphics to video tape. For example, RGB Technology has RGB/Videolink 400, 1400, and 1400A. These are video scan converters for the RGB output of the Macintosh II. One issue that normally surfaces with the NTSC boards is NTSC flicker. Flicker occurs because a television image is created by scanning alternate lines. When a computer graphic image is only one pixel wide, it is put on the screen only half of the time. This is what causes flicker. Video scan converters eliminate this interlace flicker.

For a Pencil Test-quality production, any system from any vendor requires similar amounts of time and resources to be spent. It is a simple equation in the computer animation business:  $\text{Quality} = \text{Time} + \text{Resources}$ .

Amiga animation and Pencil Test do not compare well. The Amiga solution uses 256 colors/8 bits per pixel, while Pencil Test uses 16,800,000 colors or 24 bits per pixel. Doing the shading used in Pencil Test on an Amiga results in a palette of a few main colors with many shades of those few colors. Also, be aware that many of the video products for the Amiga work at a resolution of 320 x 200 pixels. This is a fairly low-resolution graphics when compared to the Macintosh solutions using a minimum of 640 x 480 pixels. Using a product like RGB/Videolink 1400A, it is feasible to use pixel counts as high as can be purchased; that is, 2048 x 1024, 1024 x 1024, and so on.

Of interest, the developers of the top Amiga animation products are in the process of moving their applications to the Macintosh II. Many have completed the move.

## MacDFT: Description (Discontinued)

Revised: 10/7/93  
Security: Everyone

MacDFT: Description (Discontinued)

=====

Article Created: 23 August 1989

### Article Change History

-----

02/12/93 - UPDATED

- KMW now Andrew Corporation.

06/15/93 - RETITLED

- To show MacDFT is a discontinued product.

For information on currently shipping SNA products from Apple Computer, search under SNA•ps.

### Overview

MacDFT is the first complete 3270-based product from Apple Computer for the Macintosh II. It makes use of several Macintosh Coprocessor Platform (MCP) cards, such as, the Apple Coax/Twinax card and the TokenTalk card. These cards run the multitasking operating system named A/ROSE.

The software portion of MacDFT consists of three types of device drivers for the MCP cards. Two of the drivers support support CUT or DFT coax connections to 3X74 Control Units using the Caox/Twinax card. The third driver supports DFT over Token Ring with attachments to 3174 Token Ring adaptor equipped controller or Token Ring Interface Couplers (TICs) found on Front End Processors (FEPs).

The first version (September 1989) of the MacDFT terminal emulator (Version 1.0), which will ship with the Apple Coax/Twinax card, can operate as a CUT mode terminal with one session per Macintosh. A later version (December 1989, Version 1.1), to be sold as a separate product, will implement a DFT mode terminal with up to five (5) sessions per Macintosh. The sessions will be configurable via a Control Device (CDEV) in the Control Panel, which will also support communications with the cluster control unit via both the Coax/Twinax card and the TokenTalk NB card.

The MacDFT software supports IBM's IND\$FILE host file transfer system in both CUT and DFT mode. The files can be sent to Time Sharing Option (TSO) or

## ..TIL04251-MacDFT-Description\_Discontinued.pdf

Conversation Monitor System (CMS). File modes supported are text, MacBinary, and binary.

MacDFT is the first product from Apple that makes use of the Apple 3270 Application Program Interface (API). The MacDFT terminal emulator is written around calls to the API boundary and therefore has no hardware or connectivity dependencies. MacDFT, combined with the API, enables Apple to have "one application with many drivers" as an architected solution. The MacDFT application operates over Coax Type A media attached to IBM 3X74 cluster control units or compatibles. The MacDFT product is also intended to be used in conjunction with the Apple Token-Ring card. A Macintosh on a Token Ring network will be able to receive 3270 data streams from a LAN-based 3174 or a 37X5 Communications Controller or Front End Processor (FEP).

### MacDFT product elements

The MacDFT product is shipped in two packages. The hardware is referred to as the Apple Coax/Twinax card.

The software (Version 1.0) shipping in September includes:

- CUT-only CDEV Driver
- MCP Multi-tasking OS (Apple A/ROSE)
- MacDFT Terminal Emulation with file transfer
- Apple 3270 API (included with MacDFT application)

The software shipping in December includes:

- CUT/DFT CDEV Driver supporting Coax/Twinax and TokenTalk cards)
- MCP Multi-tasking OS (Apple A/ROSE)
- MacDFT Terminal Emulation with file transfer
- Apple 3270 API (included with MacDFT application)

### MacDFT application functions

By December, the MacDFT application (Version 1.1) will support the following 3270 workstation features:

- CUT terminal emulation (LU type 2 only)
- DFT terminal emulation (LU type 2 only)
- Multi-session terminal emulation using Token Ring  
(PU type 2 services with multiple LU type 2s)
- File transfer to the host using the IBM PC file transfer standard  
IND\$FILE in TSO and CMS environments.

When MacDFT is used as a CUT, DFT or Token Ring mode terminal, it provides:

A C-DEV Driver that has three modes of operation:

- A 3270 CUT driver, which supports one 3278/79 session.

- A 3270 DFT driver, which supports up to 5 3278/79 sessions.

## ..TIL04251-MacDFT-Description\_Discontinued.pdf

A 3270 Token Ring driver, which supports PU type 2 as a downstream PU on the ring and up to five (5) 3278/79 sessions per workstation.

Implemented using the Apple 3270 API.

Multifinder compatibility, with support for background processing.

Emulation of 3278/79 screen sizes: 24x80, 32x80, 43x80, and 27x132, corresponding to display models 2, 3, 4, and 5. The user can select the model number. Alternate screen size support is provided by the Apple 3270 API. This includes notification to the application if the host application changes screen size, so that the Macintosh application can make the appropriate changes.

Support for the IBM 87-key typewriter keyboard, which maps to the Macintosh extended keyboard.

An autokey feature to allow storage and playback of host application sequences such as logon sequences.

Print screen and save screen to disk file.

Copy and paste into and out of 3270 screens.

Copy table.

Color support that includes:

- Monochrome (2 color)
- Base Color (red, blue, green, white)
- Extended Color (red, blue, green, white, yellow, turquoise, pink)

Attribute support that includes:

- Protected/unprotected fields
- Normal/intensified display
- Alphanumeric/numeric data
- Auto skip
- Modified data tag

Extended attributes:

- Normal
- Blink (blink attributes are provided on the Macintosh using italics on a monochrome display and using color on an RGB display)
- Field outlining
- Reverse video
- Underline
- Extended color

File transfer that uses the IND\$FILE file transfer protocol. The IND\$FILE protocol sends full or partially full screens from the CUT presentation space to the host; the screen information is then processed by the IND\$FILE host application. When MacDFT is used as a DFT or Token Ring mode terminal, it

# ..TIL04251-MacDFT-Description\_Discontinued.pdf

provides file transfer via the Destination/Origin (DO) Structured Field file transfer protocol. This protocol relies upon 'pass-thru-data' API service requests to transfer data to and from the host.

## MacDFT unsupported functions

The CUT and DFT device drivers used by MacDFT do not support the following features:

### Standard attributes

- Light pen detectable/undetectable

### Extended attributes

- Programmed symbols including APL
- Background color
- Transparency

### Graphics

- GDDM
- Program symbols
- All points addressable (APA)
- Non-Roman (Kanji)

### Keyboards

- Data entry
- ASCII
- Text
- 102-key typewriter
- Keyboard RPQs

### Miscellaneous

- Entry assist
- Explicit partitions (DFT)
- Magnetic readers
- Convergence feature

### Special Information

MacDFT software does NOT emulate 5250 terminals even though the hardware MCP card has that capability. KMW Systems of Austin, Texas (now Andrew Corporation) announced on June 12,1989 at the Apple N & C Product rollout that they will ship a product ApLink which is 5250 terminal services with file transfer which uses the Apple Coax/Twinax MCP card.

## Apple Scanner: Not Designed for High-End Publishing

Revised: 8/23/89  
Security: Everyone

Apple Scanner: Not Designed for High-End Publishing

=====

This article last reviewed: 18 August 1989

TOPIC -----

Why doesn't the Apple Scanner support 256 shades of gray like the competition. When I took some scanned data to a publishing service for Linotronic output, I was told that my output was of poor quality and needed rescanning. I have two questions:

- 1) For Linotronic output, do third-party scanners, such as the Abaton (also known as MicroTek), have a technical advantage by offering 256 shades of grays instead of 16?
- 2) Will a ROM upgrade to the Apple Scanner address this issue in the future?

DISCUSSION -----

The Apple Scanner isn't designed as a high-end scanner. It is an attractive, low-cost, entry-level scanner that is ideal for outputting to LaserWriters, using with HyperCard and OCR applications, capturing line art, for "draft" scans to assist in document layout, and so on.

To get the best scanned output from the Linotronic, it is best to use an 8-bit scanner. The disadvantage of 256 grayscale images is the incredible amount of disk space the scanned images consume. An 8- by 10-inch image at 300 dpi with 8 bits per sample, saved without using any compression scheme, consumes upwards of 8MB of disk space. This kind of density also requires a lot of time to scan and print. The average price of an 8-bit scanner is quite a bit more than the Apple Scanner, too!

To support a greater number of grayscales, like 256 on the Apple Scanner would require more than just a new ROM; it is more a limitation of the scanner hardware itself.

The Apple Scanner has been well received by customers and reviewers, but it isn't for everyone. You may be better served by another product.

## 3270 Terminal Emulator with Asynchronous IND\$FILE Transfer

Revised: 4/11/91  
Security: Everyone

3270 Terminal Emulator with Asynchronous IND\$FILE Transfer

=====

This article last reviewed: 18 August 1989

TOPIC -----

Do you know of an asynchronous 3270 terminal emulator that also supports IBM's IND\$FILE file transfer? Apple's FT/3270 software is a possible solution, but I want to avoid installing additional host software, if possible.

DISCUSSION -----

Avatar's MacMainFrame DX supports asynchronous access to a 3270 mainframe, and their current release of software supports IND\$FILE file transfer.

Tri-Data's Netway 1000, release 6 or later, provides asynchronous access to IND\$FILE.

For more details, search the Tech Info Library under "Tri-Data" and "Avatar."

Macintosh: Foreign File Access Error Message

=====

Article Created: 18 August 1989  
Article Last Reviewed: 21 July 1992  
Article Last Updated: 21 July 1992

### TOPIC -----

I received this message when starting a Macintosh with an attached CD-ROM drive:

"No File System Access Modules could be found in your System Folder.  
Therefore, the Foreign File Access Software was not installed."

Can you explain?

### DISCUSSION -----

You get this message when you have the Foreign File Access INIT in your System Folder, but no access files.

You may have or may once have had an Apple CD-ROM drive with the appropriate software to access it. At some point, the files High Sierra File Access, ISO 9660 File Access, and Audio CD Access were removed from the System Folder. Now at startup, the Foreign File Access INIT is unable to locate them and issues that message.

System 6: Maximum Number of Fonts

=====  
Article Created: 18 August 1989  
Article Last Reviewed: 5 August 1992  
Article Last Updated: 5 August 1992

TOPIC -----

I am experiencing problems when using over 250 fonts with System 6.0.3 software on a Macintosh II. This is a standard system with Adobe fonts. Is this still a problem? I thought the maximum number of fonts problem was resolved long ago.

Are there any special precautions, like Font/DA version, to take into account?

DISCUSSION -----

A 'FONT' resource uses bits 7-14 for the font's resource ID and bits 0-6 for the font's point size. Thus, there are 256 (0-255) numbers available for font family IDs using a 'FONT' resource.

The 128K ROM introduced a new way of identifying fonts, using 'FOND' and 'NFNT' resources. This new strategy allows you to use all 15 (0-14) bits for font family IDs, giving you 32,768 possible IDs. Of these 32,768, there are 16,384 available for Roman systems.

However, in order to be compatible with the old way of identifying fonts, both 'FONT' and 'NFNT' resources can be used. There is still the limitation of 256 'FONT' resources. Therefore, the number of fonts you can install depends on which resource types the fonts use.

What seems to be the real problem, however, is that all fonts put into the System File should be installed using the Font/DA mover. The Font/DA mover will only support 200 fonts. You should use Font/DA Mover 3.8 (or later). Turning off virus detection utilities, setting RAM cache to off, and installing fonts under Finder are all prudent activities, but are

rarely essential.

If you want to use more fonts you will need to use a resource-organization utility, like Suitcase II or Font/DA Juggler Plus, which allow you to organize groups of fonts in a variety of ways, including by families into files. Then you can open just those files when you need to access those fonts. Suitcase should be able to give you as many fonts as you need. Each Suitcase file has a limit in the number of fonts you can install; however, you can have multiple Suitcase files.

For more details, search for "Fifth Generation Systems" and "3rd" or "Alsoft" and "3rd".

## Apple Scanner: Bulb Life Span

Revised: 8/23/89  
Security: Everyone

Apple Scanner: Bulb Life Span

=====

This article last reviewed: 18 August 1989

TOPIC -----

What is the life span of the Apple Scanner bulb?

DISCUSSION -----

Though Apple didn't formally test the life span of the Apple Scanner bulb, only a rough estimate as to how long they are likely to last is possible.

We specify that the Apple Scanner bulbs supplied to us by vendors last a minimum of 200 hours of continuous use at an elevated temperature of 40 degrees Centigrade. Our experience using the Apple Scanner shows that all bulbs that stopped working had been in use longer than 230 hours at elevated temperatures of 48 degrees Centigrade. This translates into a possible life span of approximately 2400 scans. The actual life span of bulbs in a user environment might be a bit longer, but we are unable to establish any life span with specific test data at this time.

## Tape Cartridge: Life Span

Revised: 8/23/89  
Security: Everyone

Tape Cartridge: Life Span

=====

This article last reviewed: 18 August 1989

TOPIC -----

I am trying determine the life span of a tape cartridge. The article says "5,000 passes". Can you give me the suggested usage limits for a tape cartridge? How many backups is that? How many times does the tape pass through the drive during a backup?

DISCUSSION -----

The tape cartridge life span can be greatly influenced by the environment you store and use them in, and by whether you back up the tapes by Volume or by File.

If you are backing up tapes by volume, your cartridge can last for a few thousand backups. This estimate is not based on any controlled study, but on the assumption that during a Volume backup, after the initial tensioning of the tape, the drive generally records information on the tape from the beginning to wherever it stops once it has completed transferring all of the data. This is usually in one or two continuous passes. Incidentally, the noise the drive makes when performing a Volume backup, changes in pitch, and variance of the volume is not from the drive stopping the tape, rewinding it, and proceeding forward--it is the drive switching tracks.

Backing up onto the tapes by File is much more stressful on the tape. The drive may have to reverse direction of the tape many times to put the files down sequentially on the tape, especially when the files are fractured on the drive. We are unable to predict the longevity of a tape used for file backups because of the great variance in the quantity of files backed up at any time, the differences in sizes, and the degree to which they are fractured. However, prudence should dictate practice when archiving data.

The operating environment also influences the tape life. Prior to using the cartridge, let it acclimate to your operating environment for

eight hours or for the amount of time it has been exposed to dissimilar conditions--whichever is less. Recommended operating environment:

|                              |                                         |
|------------------------------|-----------------------------------------|
| Temperature                  | 41 to 113 degrees F (5 to 45 degrees C) |
| Relative Humidity            | 20 to 80% noncondensing                 |
| Maximum Wet Bulb Temperature | 79 degrees F (26 degrees C)             |

Tapes should be stored out of direct sunlight and not be exposed to high temperatures.

## Macintosh: Desktop Media & the Making of Pencil Test (2 of 2)

Revised: 2/12/93  
Security: Everyone

Macintosh: Desktop Media & the Making of Pencil Test (2 of 2)

=====

Article Created: 23 August 1989

### Article Change History

-----

02/12/93 - UPDATED

- MacroMind-Paracomp now MacroMedia.

Pencil Test was modeled with Super3D from Silicon Beach Software (now Aldus Consumer Division). These 3D models were animated using MacTwixt, a Macintosh version of the public-domain animation package Twixt, developed at the University of Ohio by Dr. Julian Gomez.

Apple's Advanced Technology Graphics Group developed custom, 3D-rendering applications to render each frame of the film, adding material properties, like color, texture, smoothness, specularly, and shininess, to the geometric models (illuminated by one to four light sources and shaded by the method of Gouraud or Phong). A 24-bit Z-buffer was used to resolve the hidden surfaces. Digital bitmaps of the wood grain on the desktop, the cartoon on the mug, and the computer screen were texture-mapped onto the objects. In one scene, temporal anti-aliasing was used to create the effect of camera motion blurring.

The frames were rendered as 24-bit images at a resolution of 2160 x 1458. Each image was decimated by a factor of 3 in each dimension, using a windowed-sinc filter to reduce aliasing artifacts, to the target resolution of 720 x 486. This was then gamma-corrected and converted to (Y, R-Y, B-Y) in the CCIR-601 digital format.

Each of the approximately 5,000 frames took an average of 30 minutes to render, for a total rendering time of 2,500 hours, or 104 days. A distributed rendering program was used to produce this in parallel in a period of four days of elapsed time on a network of 25 Macintosh II computers over the EtherTalk network.

A master program parceled rendering jobs to available machines and collected and compressed the finished frames. The finished frames, totalling 3 minutes

and 10 seconds, occupied 1.4 gigabytes of a 2.5-gigabyte SCSI disk drive attached to a Macintosh II acting as an AppleShare File Server. The frames were then decompressed and transferred to an Abekas A60 digital sequence store. A Sony D-1 digital component video recorder was used to record the final video sequence off of the Abekas.

Along with the high-resolution digital video version, a Macintosh II version of Pencil Test was created by filtering every other 720 x 486 frame by a factor of 2 in each dimension with a windowed-sinc function to a target resolution of 360 x 243 (24-bit RGB). A custom-written application can replay the compressed 75MB animation in near real-time from an Apple HD80 SC SCSI hard disk on any 32-bit Macintosh II graphic interface card. The sound track for the video was created using Macintosh computers connected to music synthesizers via the Apple MIDI interface.

The score was composed and sequenced using the Performer application from Mark of the Unicorn. The sound effects were edited on the Macintosh using Sound Designer from digidesign and Opcode Patch Librarian from Opcode Systems. The effects were then cued to the video using digidesign's Cue Sheet. During final mixdown, two Macintosh computers were synchronized to the Sony D-1 digital video recorder using two Opcode Systems' SMPTE Timecode machines. One of the Macintosh systems controlled a Roland S-330 sampling instrument that played the score, while the other Macintosh controlled two E-Mu Systems' Emax sampling instruments playing the sound effects. The soundtrack was mastered directly back onto the Sony D-1.

As a comparison, the opening sequence of Steven Spielberg's television show, Amazing Stories, used a crew of 60 people. They spent 60 16-hour days working with a Cray supercomputer to produce 30 seconds of animation, or 6.5 man-years of work. We have no information on other animation programs for the Macintosh II. However, in addition to MacroMind, two companies to watch are Aegis Development Inc. and Byte by Byte.

With the general overview of Macintosh animation covered, here are some plausible, low-cost to state-of-the-art systems:

- 1) Super 3D and/or Swivel 3D, MacroMind's Director, one of the above-mentioned 8-bit color video card with NTSC and GenLock, and a high-quality VHS VCR.
- 2) Any graphics program that produces PICT2 or PICS files, TapeOp, Color-Space II, Color-Space II F/X, and a Betacam BVW-XX VTR.
- 3) Any graphics application that produces PICT2 or PICS file formats, TapeOp, Macintosh II Video Card with RAM expansion kit, RGB Technology's RGB/Videolink 400 (or 1400 or 1400A), and Sony Umatic BVW-XXX VTR.
- 4) Any graphics application, Macintosh II Video Card with RAM expansion kit, and GigaPix tape hardware system.

Starting with the first system, animation in this environment is 8-bit color running in real time. Productions created with this setup can be done relatively quick and easy. The images are created in a 3D graphics application

or in Director. If Swivel 3D or Super 3D 2.0 are used, then the 3D-image series can be moved to Director via a Scrapbook file or PICS, respectively. Once in Director, the animation is recorded in real time to video tape, or, as the animation is played back in Director, it is recorded to tape. Most production time is spent creating the artwork and creating the animation.

Either system 2 or 3 lets you do production in a frame-by-frame manner. This is the more traditional method of animation and is especially helpful when animating complex images. Complex images may slow the real-time animation process to the point of customer dissatisfaction. Using a frame-by-frame technique allows the complex images to be drawn at whatever speed is necessary for the computer, and then placed one frame at a time on the video tape. Graphics are produced in any Macintosh graphics applications. The graphics needs to be saved in either PICT2 or PICS file formats.

The TapeOp application reads either file format and records the single frame graphics image to the video recorder for the specified number of frames. This is an automated process; the TapeOp application can be started in the evening and left to work through the night.

The system 4 method for creating animation is similar to the technique used for Pencil Test. Again, a frame-by-frame technique is used. The images are created in your choice of applications. Genius provides FKEYs for saving the images in the GigaPix format. Once each of the frames for the animation has been stored to the GigaPix tape, the tape is sent to a GigaPix service bureau for transfer to an Abekas digital frame storage device. A Sony D-1 digital component video recorder records the final sequence from the Abekas. From the Sony D-1 recorder, the animation is transferred to the appropriate video format: 1-inch, Betacam, Super-VHS, or regular VHS.

Vendors of video and animation hardware and software include:

- Genius, Inc.
- Macromind-Paracomp, Inc. (now MacroMedia)
- Silicon Beach Software (now Aldus Consumer Division)
- Aegis Development, Inc.
- Master Digital, Inc.
- RGB Technology
- Mass-Micro
- RasterOps
- ComputerFriends
- TrueVision

To locate a vendors address and phone numbers, use the vendor's name as a search string.

## A/UX: Implementing Dialback To a Remote Location (8/94)

Revised: 8/23/94  
Security: Everyone

A/UX: Implementing Dialback To a Remote Location (8/94)

=====

Article Created: 23 August 1989  
Article Reviewed/Updated: 19 August 1994

TOPIC -----

This article gives the basic steps for setting up an A/UX system with dial-back capability. That is, after following these steps, you can dial into an A/UX machine from a remote location and have the machine hang up the line and dial your remote modem. Many A/UX users want this capability for security reasons.

Note: Either 4.3 UUCP or HoneyDanber UUCP needs to be implemented to have this feature.

DISCUSSION -----

- 1) Using "cu", "kermit", or other means, "login" into the remote UNIX machine.
- 2) Execute a program or a shell script saying "dialback"; the "dialback" should perform the following tasks:
  - Logout your current terminal session
  - Hang up the phone line
  - Put the originating modem in the listen mode
  - Set the proper TTY bits mode to be used as a dial-out port
  - Wait a couple of seconds
  - Clear the phone line
  - Dial the phone number the user provided
  - Execute "/bin/login" to respawn a login session.

Update note: UUCP under A/UX 3.0 is HoneyDanber. A/UX 3.0 adds F protocol to HoneyDanber, so you can communicate over X.25 networks.

An historical note: Regarding the use of `"/bin/ct"` under A/UX 1.0 (or for that matter 1.1), `"ct(1)"` is a holdover from System III, and possibly even Version 7 UNIX days. Therefore, it only implements dialer code for a DEC DN-11 dialer. The DN-11 was an early dialer for non-smart modems. `"ct(1)"` only sends the telephone number digits, because that's all it expects. There should be support for today's smart modems (or, at least, the Hayes command set) in all of `"uucp/cu/ct"`. But in A/UX 1.0 and 1.1, that is not the case. Apple needs to implement either the complete 4.3BSD UUCP, or HoneyDanBer UUCP/CU/CT to have that functionality.

Article Change History:

19 Aug 1994 - Changed title from A/UX 1.0 to just A/UX.  
17 Jun 1993 - Revised to include A/UX 3.0 information.

## GS/OS 4.0: Disk Drive Anomaly

Revised: 9/22/89  
Security: Everyone

GS/OS 4.0: Disk Drive Anomaly

=====

This article last reviewed: 22 August 1989

This article describes a configuration in which GS/OS 4.0 thinks disks are locked when they aren't or unlocked when they aren't. To see the problem "live", try the following on an Apple IIGS with one or two 3.5-inch disk drives and one 5.25-inch disk drive all daisy-chained from the SmartPort.

- 1) Start GS/OS on the 3.5-inch drives.
- 2) Insert a locked 5.25-inch disk into its drive and put it on the desktop.
- 3) Remove the 5.25-inch disk.
- 4) Insert a write-enabled 5.25-inch disk and mount it on the desktop.
- 5) Copy the locked 5.25-inch disk onto the unlocked 5.25-inch disk. When the copy process ends, try to rename the unlocked 5.25-inch disk.

The Finder thinks the disk is locked. The problem appears to be with the driver for the 5.25-inch drives and seems to be related to how GS/OS sees 3.5-inch disks. If a 3.5-inch disk is unlocked, then the "Get Info" for all 5.25-inch disks displays "Unlocked", whether the 5.25-inch disk is physically locked or unlocked. Conversely, the same is true for a locked 3.5-inch disk. If a 3.5-inch disk is locked, then the "Get Info" for all 5.25-inch disks displays "Locked". Again, it does not matter if the 5.25-inch disk is physically locked or unlocked.

The workaround for this problem is to make sure that your 3.5-inch disks are not write-protected. This lets the user make copies and rename new 5.25-inch disks without having to restart the system.

## AFP: How To Implement Record-Locking

Revised: 9/18/89  
Security: Everyone

AFP: How To Implement Record-Locking

=====

This article last reviewed: 6 September 1989

TOPIC -----

How does multi-user software (like 4th Dimension) work with regard to AFP?  
Doesn't AFP provide a record-locking feature, so that the record is locked automatically or is that part of some structure inherent in multi-user software (like 4th Dimension)?

DISCUSSION -----

The AppleTalk Filing Protocol (AFP) lets a workstation on an AppleTalk network access files on an AFP-compatible file server. AFP specifies a remote filing system that provides user authentication and an access-control mechanism that supports volume- and folder-level access rights.

AFP does not provide file-locking and record-locking features to applications automatically. File-locking may be implemented by the application if the appropriate parameter is passed to the AFP call (FPOpenFork) made by the application that opens the file. These parameters include:

|   |           |                                                                          |
|---|-----------|--------------------------------------------------------------------------|
| 0 | Read      | allows the file to be read                                               |
| 1 | Write     | allows the file to be written to                                         |
| 4 | DenyRead  | denies others the right to read the file while this user has it open     |
| 5 | DenyWrite | denies others the right to write to the file while this user has it open |

Record-locking is accomplished in a much more complicated fashion. The application may lock a record by using the AFP command "FPByteRangeLock". To do this, the application must calculate where in the file the record starts and stops. This information is then passed to the "FPByteRangeLock" command and that range in the file is locked. The record may also be unlocked by using the "FPByteRangeLock" command.

## MacX25: General Overview

Revised: 9/18/89  
Security: Everyone

MacX25: General Overview

=====

This article last reviewed: 30 August 1989

- MacX25: Introduction

First introduced on June 12, 1989 at the MacIS Conference in New York City, MacX25 is a network integration tool and a developer tool. On the network integration tool side, there are two components: MacX25 Server and MacPAD. The MacX25 Server runs on an Apple Serial NB card in a Macintosh II family. MacPAD is a connection tool that resides in the Communication Toolbox environment. The developer tool is the MacX25 Programming Library. It is the development interface that allows developers to create applications that access a packet switched network as the transmission facility. Macintosh Programmer's Workshop (MPW) Version 3.0 with MPW C is required.

The MacX25 Server behaves as a gateway that is physically connected to the packet switched network via a dial-up modem or leased line. The connection interface to the packet switched network is located on the Serial NB card (62-pin connector). There are two connection interfaces available: RS-232C and V.35. The RS-232C interface supports speeds up to 19.2 Kbps and the V.35 supports speeds up to 64Kbps.

MacX25 Server runs in background under Multifinder. The maximum number of active servers per Macintosh II is five. Other system requirements include System Software Version 6.0.3 (or later), 2 MB of RAM and the appropriate Appletalk LAN cable connector.

The server has a MacX25 Admin program (similar to the Appleshare Admin program) and should be maintained by a network administrator or by a Network Control Center (NCC). This program provides the following services:

- \* Logs the activities of the server
- \* Provides password protection
- \* Creates and modifies servers
- \* Creates and modifies user databases
- \* Selects and modifies X.25 parameter files

- \* Builds and maintains a Master Address Book

#### - MacPAD

MacPAD enables an asynchronous terminal, such as a Macintosh Plus or SE, to interact with a host system. MacPAD packetizes characters transmitted to the server/network and de-packetizes characters received from the server/network.

MacPAD communicates with the server over the Appletalk LAN, whether that be Localtalk, Ethertalk, or Tokentalk. This allows users with a terminal application that uses the Communication Toolbox to place a call to any subscribed service on the packet switched network.

System requirements include a Macintosh Plus, Macintosh SE, Macintosh SE/30, or Macintosh II family with System Software Version 6.0.3 or later and the appropriate Appletalk LAN cable connector. A terminal service application that uses the Macintosh Communication Toolbox is also required.

#### - MacX25 Programming Library

MacX25 Programming Library is a C routine toolkit that allow users to connect and disconnect from the server, and to query server status and circuit information. A packet-level interface that uses control blocks is provided for developers who require maximum control. A higher level logical packet interface performs data translation and formatting services, creates X.25 packets, and relieves the programmer of some lower-level tasks.

Some examples of applications that can be developed include electronic mail systems, sales order systems, inventory control and processing, database inquiries and retrievals, and credit card verification.

System requirements include a Macintosh Plus, Macintosh SE, Macintosh SE/30, or Macintosh II family with System Software Version 6.0.3 or later and the appropriate Appletalk LAN cable connectors.

## Macintosh: System Crashes and Basic Troubleshooting (2 of 2)

Revised: 4/8/94  
Security: Everyone

Macintosh: System Crashes and Basic Troubleshooting (2 of 2)

Article Created: 18 September, 1989  
Article Reviewed/Updated: 8 April 1994

(Continued from previous article: "Macintosh: System Crashes and Basic Troubleshooting (1 of 2)")

WHAT CAUSES A CRASH - A PROGRAM TO NO LONGER RUN - UNEXPECTEDLY QUIT?  
There are many causes for problems of this nature, leading among them:

- Corrupted application

The application you are trying to use may be corrupted. This can occur on a floppy if the floppy is damaged by being stored in extreme heat or cold areas, near magnets, etc. On a hard drive, it may be that the sector on the drive has become corrupted, or one or more of its files may have been accidentally deleted. Delete the application and reinstall it.

- Application Wars

Occasionally, you may run into two or more applications, or combination of applications and DA's, Extensions, or CDev's that simply refuse to coexist in harmony. This is difficult to troubleshoot because there may be many factors interacting with each other and the problem may be intermittent, occurring only if the applications were opened in a specific order, or if a certain DA had been run sometime prior to application launch in the same work session, etc. Your solution is to remove any add-on programs (cdevs, inits, da's) that are contributing to the problem; learn not to run them at the same time; get in touch with the software vendors for assistance and fix.

- Multiple System Software Schizophrenia

Leaving the best and most common cause for last - multiple copies or versions of System Software WILL cause you to experience repeated and multiple system crashes, system freezes, peculiar and highly unusual headaches of the finest kind. NEVER, EVER, UNDER ANY CIRCUMSTANCES EVER have more than one version of System Software on your disk or disk drive. Learn good housekeeping habits. The only things that belong in your system folder are your system software, device drivers, inits, and other related programs. If you find system or

finder anywhere else, TRASH IT!

It is EASY to inadvertently clutter your hard drive with multiple copies. Every time that you copy software up to your hard drive, you may be copying System Software with it. Most applications you purchase come with System Software on the disk, or on one of the disks if it is a multi-disk package. Make sure you do NOT copy the System Software to your hard drive - and as a double check - get into the habit of periodically using Find File to do a search on all your connected drives for "System" and "Finder." If you find multiples, get rid of them. Keep only the officially installed System Software in your System Folder.

## SYSTEMATIC TROUBLESHOOTING PROCEDURES BEFORE PANIC

1. If your problems started after installing new Extensions or Control Panels, remove them to determine if they are incompatible.
2. If your problems started after installing new System Software, check with software vendor to determine if there is a compatibility problem.
3. If your problems started after installing new application software, try running from the floppy to make sure the software is in good working order; check documentation to determine that you are using system software with which it is compatible; check with software vendor to determine if there is a compatibility problem or known bug.
4. Try quitting other applications.
5. Try launching the problem application first.
6. Make sure that the application you are trying to run has not been deleted or damaged. Delete the copy on drive and reinstall.
7. Check memory allocation and increase if necessary.
8. Replace system software. Use the installer on your original system software diskettes or CD ROM.
9. Rebuild your desktop.
10. Create a folder within your system folder and call it "Suspects". Put all your inits, cdev's, startup and control panel programs in that folder and restart your system. If your crashes or unreliable operation problems disappear, you can be fairly confident that one of the "suspects" was causative. Replace the "suspects" to your system folder level ONE AT A TIME, (rebooting your system after each time) and run your system for a day or two or longer to make sure the problem doesn't come back. Now replace another of the suspects until you begin to have crashes again. Once you start to crash, you can be fairly certain that the last reinstated add-on program is the culprit. Get rid of it.

Remember - while not necessarily likely, it is not unheard of to be plagued with more than one causative factor when you have crashing problems. Keep working at it until you've eliminated all possibilities.

If you have investigated all of the procedures above, then you have justification in believing that you may be looking at a hardware problem. Consult your local Apple Authorized service provider and have your computer checked out.

HELPFUL HINT: When your system freezes, if you have your programmer's switch installed, you MAY be able to get back into your program long enough to save off whatever you were working on before, for the sake of safety, rebooting and starting again. Here is what you do:

Press the first button on the programmer's switch (the one with the circle on it, the triangle will restart your computer). You will be taken into the monitor and you will see a carat ">" prompt:

Type the following:

```
SM 0 A9F4      (press RETURN)
G 0            (press RETURN)
```

This procedure will not work all the time, but will work often enough to permit you to quickly do a Save or a Quit, then permit you to reboot your system so that you will not lose your valuable data.

Remember, you can always replace your system software, add on software and applications. But the ONLY way you can replace your data is if you are conscientious about BACKING IT UP routinely.

## Apple Data Modem 2400: Pinouts and Hardware Description

Revised: 9/18/89  
Security: Everyone

Apple Data Modem 2400: Pinouts and Hardware Description

=====

This article last reviewed: 29 August 1989

### Front Panel

-----

- Green LED  
This indicates that the modem is powered on and the serial signal from the computer is routed to the modem. (Normal startup state)
- Amber LED  
This indicates that the modem is powered on and the serial signal is passing through the modem and is being routed out of a second serial port on the modem.
- Mode Switch  
This is used to toggle between the modem and the pass-through serial ports.
  - The Mode switch state is indicated by the two LEDs.
  - The Mode switch is situated between the LEDs on the front panel.
  - The Mode switch is inactive when the modem is connected to a remote modem.
  - The Mode switch can be used to reset the modem to the factory settings. If the Mode switch is held down during power-up, the modem reads its settings from the ROM. (This is the hardware equivalent of the "AT&F" command.)
  - There is no software control of the Mode switch.

### Right Side Panel

-----

- Volume Control Lever  
This is used to control the volume of the speaker built in to the bottom of the modem. There is a detent that indicates the center of the volume range. Move the lever forward or backward to adjust the volume.

Back Panel

-----

- On/Off Switch

This switch controls the power from the AC adapter to the modem circuitry.

- Telephone Line RJ-11 Jack (RJ-11 Socket icon)

This provides a port to connect the modem to the wall outlet.

- Telephone Set RJ-11 Jack (Telephone icon)

This provides a port to connect the modem to a telephone set. This port is disconnected when the modem is using the telephone line.

- Modem Mini-DIN 8-Pin Serial Port (Macintosh icon)

This connects the computer to the modem. It uses the standard Macintosh serial port pinout.

| Pin   | Pin Name | Definition         |
|-------|----------|--------------------|
| ---   | -----    | -----              |
| 1     | Hsko     | CTS from modem     |
| 2     | Hski     | DTR from local CPU |
| 3     | TxD-     | Transmit data (-)  |
| 4     | Sgnd     | Signal ground      |
| 5     | RxD-     | Receive data (-)   |
| 6     | TxD+     | Transmit data (+)  |
| 7     | GPI      | DCD from modem     |
| 8     | RxD+     | Receive data (+)   |
| Shell | Ground   | Chassis ground     |

Note: This product works with both the Macintosh and Apple II computer families.

- Modem Mini-DIN 8-Pin Serial Port (Telephone Handset icon)

This allows a serial device to be daisy-chained to the modem. This port is disabled when the modem is in use (indicated by green LED) or when the modem is powered off.

- This port is not rated for AppleTalk transmission speeds (the maximum speed is 56.7 kilobits per second); therefore, it cannot be used to pass-through AppleTalk signals.

- 5-Pin DIN Power Connector

This allows a wall-mounted AC adapter to be connected to the modem.

- Security Cable Socket

This is used to secure the modem.

## AFE: Problems Translating Into RFT and DCA Formats

Revised: 9/18/89  
Security: Everyone

AFE: Problems Translating Into RFT and DCA Formats

=====

This article last reviewed: 31 August 1989

TOPIC -----

I have had numerous experiences using Apple File Exchange to translate RFT files where the translator generates an error stating that the file is not a standard RFT file format. I've seen this many times with files brought over from a 5520 or DisplayWriter.

Now, I am trying to create a DisplayWrite 4 file on a IBM PC-AT and save it to a 3.5" 720K disk. AFE translates it fine. I do the same thing on my PS/2 Model 60, and the error occurs. If I copy that file to my IBM AT, then resave it, the error remains. I am running the same versions of DisplayWrite on both machines.

I'm thinking of trying the DataViz translators. The RFT translator seems much more robust (it has never flagged any errors where Apple's supplied translator does).

Two questions:

- What is the difference between the supplied RFT-to-MacWrite translator and the one available from DataViz?
- Do you have any ideas on why a file created on the Model 60 would be different from the file created on the IBM AT?

DISCUSSION -----

The RFT translator that currently ships with AFE is not compatible with DCA/RFT documents created by DisplayWrite 4 or other software packages that use the more recent releases of the DCA standard. Apple is evaluating whether to create a new version of the translator that is compatible with the recent releases of the DCA standard.

There should be no difference in the files created by DisplayWrite 4 on any IBM-compatible computer. We cannot begin to guess why the files appear to be different; we suspect that they aren't.

## Apple Data Modem 2400: Overview

Revised: 9/18/89  
Security: Everyone

Apple Data Modem 2400: Overview

=====

This article last reviewed: 29 August 1989

On June 12, 1989, Apple introduced the Apple Data Modem 2400. It is a 2400 bits per second (bps) external modem for the Apple II and Macintosh family of computers.

The Apple Data Modem 2400 supports the standard 2400/1200/300 bps modem protocols Classes 1 through 4 error correction protocols and is fully Hayes-compatible.

### Features

-----

- Two serial ports for connecting to the computer and to daisy-chain a serial device, such as the AppleFax Modem.
- Two RJ-11 ports to connect to the wall outlet and a telephone handset.
- A wall-mounted AC power adapter that plugs into the modem.
- An on/off switch built in to the modem.
- A built-in speaker with external volume control.
- A security slot.
- Nonvolatile RAM to store modem settings.

### Support Issues

-----

- It is possible to plug the AppleFax Modem or Apple IIc power supply into the Apple Data Modem 2400. If this is done, the modem will not power up, but it will not cause any damage to the modem or power supply.
- Only the two inner lines (tip and ring) of the RJ-11 jacks are passed through. This may cause problems with certain PBX systems that use the outer two lines for special-feature signaling. In this situation, it is best to have separate telephone lines for the modem and the telephone set.
- Unlike the Apple Personal Modem, this unit uses nonvolatile RAM to store the modem settings, which means that the modem does not automatically power up with the factory settings. The modem can be forced to the factory settings by either issuing the AT&F command or holding down the

Mode button on the front panel during power-up.

- Because the serial port is rated for a maximum speed of 56.7 kilobits per second, AppleTalk devices cannot be daisy-chained to the modem.
- The ports for the telephone line and telephone set cannot be interchanged because the telephone set port is disconnected when the modem is in use. The same applies to the serial connections because the signals are directional. The ports must be used as marked.

#### Availability

-----

The Apple Data Modem 2400 will be sold only by authorized Apple Desktop Communications dealers.

## Apple Data Modem 2400: Specifications (Discontinued)

Revised: 6/20/94  
Security: Everyone

Apple Data Modem 2400: Specifications (Discontinued)

=====

Article Created: 18 September, 1989

### I. Technical Specifications

#### A. Regulatory

1. FCC Registration Number: BCG794-12381-DM-E
2. Ringer Equivalence Number: 1.1B
  - a. The total number of ringer equivalence numbers on any one telephone line cannot exceed 5.0.
3. Canadian Load Number: 7

#### B. Self-Test

1. The modem executes a brief self-test when first powered up, and sounds two beeps if all tests pass.
  - a. This test and response cannot be disabled.

#### C. Data Format

1. Protocol: Asynchronous
2. Character Length
  - a. 7 data bits
    - 1) Stop bits: 1 or 2
    - 2) Parity: Odd, even, fixed: mark/space
  - b. 7 data bits
    - 1) Stop bits: 2
    - 2) No parity
  - c. 8 data bits
    - 1) Stop bits: 1 or 2
    - 2) No parity
3. Mode: Full duplex

#### D. Compatibility

1. Complete set of Hayes modem command instructions

#### E. Error Correction

1. Microcom Network Protocol (MNP) Classes 1 through 4

F. Transmission Speeds

1. For all speeds
  - a. Tolerance in character asynchronous format (DTE data rate)
    - 1) +1.0%
    - 2) -2.5%
  - b. Tolerance in modulation rate
    - 1) +/- 0.01%
2. 2400 bits per second (bps)
  - a. Standard: V.22bis
  - b. Modulation: Quadrature Amplitude Modulation (QAM)
3. 1200 bits per second (bps)
  - a. Standard: V.22A/B, Bell 212A
  - b. Modulation: Differential phase-shift keying (DPSK)
4. 300 bits per second (bps)
  - a. Standard: Bell 103
  - b. Modulation: Differential phase-shift keying (DPSK)

G. Operating Modes

1. Auto or manual dial (including redial)
  - a. Tone: DTMF (Dual-Tone Multi-Frequency--"Touch Tone")
    - 1) Frequency tolerance: +/- 1/0%
    - 2) Tone balance: Within 3dB
  - b. Pulse (Rotary)
    - 1) Dialing duty cycle: 39%/61% mark/break ratio
    - 2) Dialing rate: 10 pps
2. Auto or manual answer

H. Receiver Dynamic Range

1. -10 to -45 dBm, full duplex

I. Transmitter Level

1. -10dBm +/- 1dB, fixed

J. Parameter Memory

1. Nonvolatile RAM for storing settings
  - a) 10,000-cycle life

K. Command Buffer

1. 40 characters, not including AT or any following spaces, dashes, or parentheses.

L. Interface

1. RS-422-A, with mini-DIN8 connector (standard Macintosh pinout)

M. Environmental Specifications

1. Operating temperature: 32-104 degree F (0-40 degree C)
2. Relative humidity: 95% noncondensing

N. Line Monitoring

1. Software: Print status messages to computer
2. Audio: Built-in speaker with external volume adjustment

- O. Power Source
  - 1. AC input (U.S. and Canada)
    - a. 110V +/- 10%, 60 Hz
- P. Power Consumption

## VAX-to-Mac Connectivity: Starting Sequence is Critical

Revised: 9/18/89  
Security: Everyone

VAX-to-Mac Connectivity: Starting Sequence is Critical

=====

This article last reviewed: 29 August 1989

When running the following software on the same VAX:

- VAX 8800
- VMS 5.02
- AppleTalk 2.0
- PACER 4.5
- ALISA 3.2
- PCSA 2.1

the order in which these programs are started is critical. Otherwise the Macintosh computers on the network will not see these services, or the PACER and ALISA products will not start. If AppleTalk for VMS is started before PACER when attempting to start PACER, it will fail; AppleTalk should be the last product started. These are undocumented but known problems with PACER and ALISA.

Here is a recommended starting sequence:

1. DECnet
2. PCSA
3. PACER
4. ALISA
5. ATALK for VMS

## 4th Dimension: How to Customize the CLUT 9/89

Revised: 3/15/93  
Security: Everyone

4th Dimension: How to Customize the CLUT 9/89

=====

Article Created: 18 September 1989

Some people have noticed a problem with the presentation tools with 4th Dimension when using splash screen that needed colors that weren't in the default palette. The following workaround is usefull if you need to change a few colors (for a Corporate logo, for example).

1. Copy the palette for the image using ResEdit
2. paste the palette for the image into 4th Dimension
3. Change the CLUT ID (color lookup table) to 0 so that it becomes the default palette on application launch. This way

Unfortunately, this solution means that you are stuck with that palette until changed in the application (for all files). To minimize this drawback, try starting with the default system palette and change only some obscure, less used colors in that palette to the ones you want and leave the other standard colors alone.

## X.25: A Technical Overview

Revised: 9/18/89  
Security: Everyone

### X.25: A Technical Overview

=====

This article last reviewed: 30 August 1989

- X.25

X.25 is a CCITT recommendation for a synchronous interface between a data terminal equipment (DTE) operating in a packet mode and the data circuit terminating equipment (DCE) on the public data network. The elements of the interface is defined independently as:

Physical - the mechanical, electrical, functional, and procedural characteristics to activate, maintain, and deactivate the physical connection between the DTE and DCE.

Link - the link access procedure for data interchange across the link between the DTE and the DCE.

Packet - the packet format and control procedures for the exchange of packets containing control information and user data between the DTE and the DCE.

These three levels are associated with the first three levels in the International Standards Organization (ISO) Open System Interconnect (OSI) Reference Model.

- Physical

The interface characteristics for a DTE connected to a packet switched transmission service by a dedicated circuit or by a circuit switched network is defined in Recommendation X.21 and X.21bis (V.24). Recommendation X.21 is only for connections via a circuit-switched data network while X.21bis can be used for connections via a circuit-switched data network and a telephone network.

- Link

The Link Access Procedure, LAP and LAPB, is the protocol and the frame format is High-level Data Link Control (HDLC). LAPB defines procedures for link set-up, error control, flow control, and link disconnect. The frames used within the LAPB ensures error-free packets on the access link.

- Packet

The packet level procedures pertain to virtual calls on the X.25 access link, and is independent of the internal protocol of the packet switched network. Procedures are defined for the setting up and clearing of switched virtual circuits, data transmission, and restart of switched and permanent circuits.

The packet format includes a user facility field which allow users to subscribe to various features such as Closed User Group, Reverse charging, and fast select.

## **X.3, X.28, X.29: CCIT Parameters and Acronym Glossary (9/94)**

Revised: 9/2/94  
Security: Everyone

X.3, X.28, X.29: CCIT Parameters and Acronym Glossary (9/94)

=====

Article Created: 30 August 1989  
Article Reviewed/Updated: 2 September 1994

TOPIC -----

This article describes X.3, X.28, X.29: CCIT Parameters and Acronym Glossary.

DISCUSSION -----

CCITT Recommendation X.3, X.28, and X.29 define how an asynchronous (start-stop) terminal connects to a synchronous packet switched network. A Packet Assembler/Disassembler (PAD) is employed to perform the X.25 functions that the asynchronous terminal cannot manage by itself. The PAD can reside in the network or at the DTE end. X.3 describes the parameters that the PAD uses and can be modified by the terminal and host. There are 22 parameters defined in the CCITT Red Book:

- 1) Escape from Data Transfer - if enabled, tells the PAD what key is used to toggle between the data transfer mode and command mode.
- 2) Echo - decides whether characters sent from the asynchronous terminal should be echoed.
- 3) Data Forwarding Signal - tells the PAD which char(s) mean that it is time to assemble and send a packet.
- 4) Idle Timer Delay - if enabled, tells the PAD that if no char(s) have been sent from the asynchronous terminal after the specified time, packetize and send the data in the input buffer.
- 5) Ancillary Time Control - decides whether flow control is used for data sent from a terminal with an attached floppy disk or data storage medium to the PAD.
- 6) PAD Service Signals - decides whether Service signals are to be sent to the terminal. Service signals are sent by the PAD to the operator in response to the commands sent by the operator.

- 7) Procedure on Break - defines the resulting action when the operator has hit the break key.
- 8) Discard Output - used together with parameter 7. Set by the X.25 computer to tell the PAD whether any data in the output buffer should be discarded or sent to the terminal.
- 9) Padding after CR - if enabled, specifies the number of padding characters to insert after a CR when transmitting to the terminal.
- 10) Line Folding - if enabled, inserts a CR after a predefined number of chars in the input buffer.
- 11) Terminal Data Rate - read-only parameter for the operator to view the speed of the asynchronous terminal.
- 12) Flow control of the PAD - If enabled, allows the terminal to control the data flow from the PAD.
- 13) Linefeed Insertion - if enabled, tells the PAD when to insert a linefeed after CR.
- 14) Linefeed Padding - if enabled, specifies the number of padding character to insert after an LF is sent to the terminal.
- 15) Editing - defines whether editing of the data in the PAD input buffer, while in data transfer mode, is permitted. Parameter 16, 17, and 18 define which keys are to be used for editing.
- 16) Character Delete - defines which character is used to mean char delete.
- 17) Line Delete - defines which character is used to mean line delete.
- 18) Line Display - defines which character is used to display a line of text. Useful when the user is editing text.
- 19) Editing, PAD Service Signals - defines the character the PAD will respond with when it receives a char delete or line delete from the terminal.
- 20) Echo mask - specifies which characters are not to be echoed.
- 21) Parity Treatment - defines the manner in which the PAD treats the parity bit, bit 8.
- 22) Page Wait - if enabled, defines the number of LFs the text can contain before the PAD waits for a signal from the terminal to proceed with data transmission. Allows time for a new sheet of paper to be fed into a printer or to store received chars on a diskette.

X.28 defines the interface, mainly the command language, between the asynchronous terminal and PAD. These commands enable the following functions:

- \* Set up and clear of a virtual call
- \* Select a profile that suits the terminal
- \* Modify the X.3 values
- \* Read the values of the X.3 parameters
- \* Send an Interrupt packet
- \* Query the status of a virtual call
- \* Request reset of a virtual call

X.29 is the protocol between the PAD and the X.25 terminal/host. PAD messages are used by the X.25 host to set or read X.3 parameters in the PAD and to receive an indication that the terminal has sent a BREAK and an INVITATION TO CLEAR.

## MPW: Projector Is Macintosh Equivalent of Panvalet on a PC

Revised: 6/29/90  
Security: Everyone

MPW: Projector Is Macintosh Equivalent of Panvalet on a PC

=====

This article last reviewed: 30 August 1989

TOPIC -----

Is there a program for the Macintosh that is similar to Panvalet for the IBM?

DISCUSSION -----

Panvalet is used for software development project management on PCs. To locate a similar program on a Macintosh, one doesn't have to look any further than MPW 3.0, which contains Projector. Projector is an easy-to-use collection of built-in MPW commands and windows that help programmers, individually and in teams, to control and account for changes to all the files (documentation, source, applications, and so on) associated with a software project.

Macintosh: How To Get Localized System Software and Hardware

=====

This article last reviewed: 30 August 1989

TOPIC -----

Where can I get for the Macintosh:

- 1) The Spanish language system tools.
- 2) The Spanish language keyboard.
- 3) A list of Spanish software.

DISCUSSION -----

- 1) The Macintosh System Software localized in Spanish is available through APDA.
- 2) International keyboards can be ordered through your Customer Support Representative at the distribution center. Because Apple USA doesn't regularly stock International keyboards, you might want to place your request in advance of your need, due to the amount of time it can sometimes take to acquire. Generally speaking, if you have a good source, it is typically faster to obtain International components in those countries.
- 3) This might be more difficult to acquire. We are unaware of any USA-based companies that distribute International software domestically. Of all of our previous inquiries, CLARIS was the only company we contacted that was investigating doing so. Alternatives include purchasing software from a computer store doing business in that country.

## AppleFax Modem: Reception Problem May Be Due to Line Noise

Revised: 9/18/89  
Security: Everyone

AppleFax Modem: Reception Problem May Be Due to Line Noise

=====

This article last reviewed: 30 August 1989

TOPIC -----

I have been having a number of problems with the AppleFax Modem while receiving from a NEC model NEFAX Bit-1 to my Macintosh SE/30.

The problem was when I was receiving from the NEC Fax; I was able to open and view the document, but it was nothing but dots down the center of the page. The document was 227K.

I had the sending end retransmit and was able to read the document the second time with no problems, but this time it was 127K. Previously, I had been unable to read an AppleFax document although it showed up as an AppleFax Document.

Is there a problem with this configuration or with this transmitting Fax? Have you had any reports of a similar nature? Is there anything I can do?

RESPONSE -----

Since the problem is intermittent, we suspect that line noise is the cause--not an incompatibility between the AppleFax Modem and the NEC Fax machine. If there was an actual incompatibility, you would not be able to receive the document successfully. The AppleFax Modem has the capability to drop down from 9600 baud to 4800 baud in the case of line problems, but it is not uncommon to have connections that do not support 4800 baud reliably. We suspect that this had happened in this case, and the only suggestion we have is to ensure the use of clean lines from the transmitting machine to the modem.

## AlisaShare: Increasing Finder Requirement

Revised: 9/22/89  
Security: Everyone

AlisaShare: Increasing Finder Requirement

=====

This article last reviewed: 30 August 1989

The mysterious "growing Finder" problem appears to be an AlisaShare file named ASROOT.CAT. This is a binary file used as an index datafile. ASROOT.CAT is a root level directory that writes entries for every file written to a specific volume. ASROOT.CAT is the file written to the Macintosh Finder for desktop information.

ASROOT.CAT is initially allocated 32K (64 blocks) for its contents, which in typical environments, would not be a problem. However, using a remote VAX volume (DOCUMENT+, Virtual Files) makes this transactional in nature--an application that more resembles a database. As DOCUMENT+ writes transaction files on Virtual Files, ASROOT.CAT is updated with the new file index entry. As the transaction files are deleted on Virtual Files, the associated index entries in ASROOT.CAT are not purged. Consequently, ASROOT.CAT continues to grow, which, in turn, forces the Finder requirements to increase respectively.

## AppleTalk for VMS: Concurrent User Limit

Revised: 9/18/89  
Security: Everyone

AppleTalk for VMS: Concurrent User Limit

=====

This article last reviewed: 30 August 1989

TOPIC -----

Under AppleTalk for VMS, which is AlisaShare, am I still limited to 50 concurrent users? Does this have anything to do with AppleTalk's 128-socket limit? With two sockets per node and some overhead, this leaves an absolute maximum of 62. How accurate is this, but more importantly, will this limitation ever be addressed in future versions of AppleTalk?

DISCUSSION -----

The number of concurrent users allowed on a server is defined by the developer of the server. In the case of AppleTalk for VMS-based servers, there are ways to extend the number of users beyond the limitations set by the number of sockets per node.

There actually is nothing that limits an AFP server to having one connection per socket. AppleShare uses a one-client-per-socket method to simplify bookkeeping since the machines it is running on cannot support enough users to require multiple users per socket. The processing power and disk performance usually provide the limitations of a server's capabilities.

The number of sockets allowed per node is not changing in AppleTalk Phase II. In both Phase I and Phase II, the socket number is represented as a byte, which gives 256 possible values: 128 of these are reserved, leaving 128 for dynamic socket allocation. Changing this field to a word size would require a major change to many of the routines and protocols of AppleTalk, beyond even the scope of the changes being implemented in AppleTalk Phase II.

## AppleShare File Server: Macintosh SE Versus Macintosh SE/30

Revised: 10/4/89  
Security: Everyone

AppleShare File Server: Macintosh SE Versus Macintosh SE/30

=====

This article last reviewed: 30 August 1989

TOPIC -----

Is there a performance increase when using a Macintosh SE/30 as an AppleShare file server instead of a Macintosh SE? Are there any benchmarks that illustrate a performance increase?

DISCUSSION -----

The question as to whether or not there will be a performance increase when using a Macintosh SE/30 instead of a Macintosh SE as a file server depends on where the bottleneck is for the network. If your network is currently waiting for the server, then using a Macintosh SE/30 will increase the performance. If the network itself is sending packets slowly, the Macintosh SE/30 will not help.

There are quite a few advantages to using a Macintosh SE/30 instead of a Macintosh SE as a file server if your server is the bottleneck. First of all, the CPU in the Macintosh SE is the MC68000, which runs at 7.8336 MHz. The Macintosh SE/30 has the MC68030, which runs at 15.6672 MHz. This, obviously, will speed up anything that requires processing time.

Secondly, the SCSI hard drive access time is much faster. The Macintosh SE uses a 2:1 interleave. The Macintosh SE/30 uses a 1:1 interleave because the processor is fast enough to handle the information at that transfer rate. Therefore, the access of any given hard drive is faster on the Macintosh SE/30 than the same hard drive on the Macintosh SE, which is important for servers.

Additionally, the Macintosh SE/30 has a faster hard drive than the Macintosh SE. The Macintosh SE, which has an HD20 SC, has an average access time of 65ms. The Macintosh SE/30, which has the new 3.5-inch HD40 SC or HD80 SC, has an average access time of 20ms. This, along with the faster interleave, gives a much faster overall SCSI hard disk access time.

Finally, the Macintosh SE/30 has the same logic board as the Macintosh IIX. Because of this, as with the Macintosh IIX, if there is more than 1MB of RAM, the AppleShare File Server allows up to 50 users to be logged on to it, rather than the 25 users allowed with the Macintosh SE.

## ProDOS 8: How To Set, Save, and Retrieve Date/Time Data

Revised: 9/18/89  
Security: Everyone

ProDOS 8: How To Set, Save, and Retrieve Date/Time Data

=====

This article last reviewed: 30 August 1989

TOPIC -----

I have a third-party clock device connected to the game port of an Apple IIe. I also have a BASIC routine that returns the time and date in a variable. The problem is that the routine does not store the date and time in a place where other ProDOS programs (that is, AppleWorks) can access them. Is there a standard memory location and format for storing the time and date so that all other applications can retrieve it? I'm assuming that most ProDOS programs use the "GetTime" call. Is it possible to preload the memory locations that "GetTime" references?

DISCUSSION -----

There is a standard memory location and format designated by ProDOS for the Date/Time data.

ProDOS has a built-in clock driver that queries a clock/calendar card for the date and time. After the routine stores that information in the ProDOS Global Page (\$BF90-\$BF93), either ProDOS or your own application programs can use it.

The locations reserved by ProDOS for the Date/Time are \$BF90-\$Bf93. The format looks like this:

|       |                |        |                |
|-------|----------------|--------|----------------|
|       | 49041 (\$BF91) |        | 49040 (\$BF90) |
|       | 7 6 5 4 3 2 1  |        | 7 6 5 4 3 2 1  |
| Date: | Year           | Month  | Day            |
|       | 49043 (\$BF93) |        | 49042 (\$BF92) |
|       | 7 6 5 4 3 2 1  |        | 7 6 5 4 3 2 1  |
| Time: | Hour           | Minute |                |

The ProDOS clock driver expects the clock card to send an ASCII string to the GETLN input buffer (\$200). This string must have the following format (including the commas):

mo,da,dt,hr,mn

where:

mo is the month (01 Jan...12 Dec)

da is the day of the week (00 Sun..06 Sat)

dt is the date (00 through 31)

hr is the hour (00 through 23)

mn is the minute (00 through 59)

For example, 07,04,14,22,46 represents Thursday, July 14, 10:46 PM. The year is looked up in a table in the clock driver.

To support clock cards that do not follow the ProDOS protocol defined above, you can locate your code in a number of places. The cleanest solution is to replace the ProDOS routines with your own, if they fit. If you look at \$BF07, \$BF08, you will find the location to put your code. There is room for 125 bytes.

There is more information about this subject in the ProDOS 8 Technical Reference Manual, Chapter 6, "Adding Routines to ProDOS", beginning on page 104.

The disadvantage is that once the date/time is loaded by your routine, there is no way to update it without returning to your own program to reset the memory locations with the new date/time. This would get pretty cumbersome if done often.

## Macintosh: System Crashes and Basic Troubleshooting (1 of 2)

Revised: 4/8/94  
Security: Everyone

Macintosh: System Crashes and Basic Troubleshooting (1 of 2)

Article Created: 9 August 1989  
Article Reviewed/Updated: 8 April 1994

TOPIC -----

One problem that every Macintosh user faces sooner later is a system crash, freeze, or other unexpected event. Depending on the user's knowledge and familiarity with his system, such an event may simply be shrugged off with no great concern, or lead to phone calls or sudden visits to the local Apple Authorized Dealer. All too often the user immediately suspects a hardware failure and panics, thinking of hundreds of dollars of repair costs. Usually, the problem is not related to hardware failure. The purpose of this article is to help users understand what is happening, help them to troubleshoot their problem, resolve it, or to fairly conclusively determine that they may in fact be looking at a hardware failure and be in need of service.

DISCUSSION -----

### HOW TO START TROUBLESHOOTING

The most useful thing you can do for yourself and for anyone else who may become involved in helping you troubleshoot your system, is to set up a problem log in which you record exactly what was going on when the problem occurred. The format below should prove useful:

- Which version of system software is being used
- Program being run (include version number)
- Other Applications open at the time
- List all Extensions, Control Panels
- What were you doing EXACTLY when the problem occurred
- What was the result (freeze, reboot, crash, error message, etc.)
- What you tried to do to get out of it and with what results
- Did you have to reboot?
- Did things work okay after reboot

If you experience multiple crashes and begin the troubleshooting cycle below, note what you do and with what results.

If it becomes necessary for you to take your system to your dealer to assist you with the troubleshoot, this information will be helpful for explaining the problem.

WHAT CAUSES A CRASH - A PROGRAM TO NO LONGER RUN - UNEXPECTEDLY QUIT?

There are many causes for problems of this nature, leading among them:

- Corrupted System Software from a previous crash or incompatible add-on

Although this sounds like a round-robin, and in fact is, the plain truth is that any system crash could corrupt your application or System Software to some degree which, if not corrected, will continue to haunt you until the problem is determined and corrected. The solution is to reinstall System Software and, as a matter of good habit, the application. It is usually wise to err on the side of precaution than not - and good practice to keep your copy of System Software nearby so that you can reinstall after any serious crash. An incompatible extension or Control Panel after being run, even if removed, may leave "bits and pieces" of itself behind. Reinstalling System Software will correct this problem as well.

- System and Application Version Incompatibility

Not all versions of System Software and application software are compatible. Most applications that you purchase will clearly indicate what version of System Software is required to permit the program to run correctly. If you are using an older version of System Software, you may have problems. If you are running current System Software, but using an old version of application software you may run into problems. Occasionally, when System Software is updated, some previously functioning applications may fail to run, crash, or fail to perform reliably. This is a compatibility problem, you have only two alternatives: first, revert to an older version of System Software under which the application ran well; and/or get in touch with the software vendor and notify him of the problems, and inquire about the availability of a "patch" or upgrade.

- Out of Memory condition - real or "imagined"

Some programs are "memory hogs": You may discover that you have simply not enough memory to open, or to run the application with all features working correctly. Some programs will fail to open at all; others will open and run for a while until you try to do a cut and paste, edit, print, sort, etc., operations which require additional memory. Your available options are to close another application to permit you to use the one that is crashing and/or obtain more memory.

In some instances, the "out of memory" condition is not real. This situation may exist when a program requires that you have a certain amount of "contiguous" memory available. While you may show that you have 1MB available, and the program only needs 267K, you may not have 267K of memory all in one chunk. Close the other applications you have open, then launch the program you had problems with.

Occasionally a complete system restart will be necessary. In some situations, your application may not have enough memory allocated to it to permit it to run correctly: This includes your finder. Select the application by single-clicking on it. Do a "Get Info" from the Menu Bar (or Command-I). If you

do not have as much memory allocated as is recommended, increase to the recommended amount. If you have the correct allocation, try doubling it to see if that helps.

### - Extension or Control Panel Compatibility Problem

Some add on software, such as Extensions, CDevs, and DAs may not have been written to permit them to be compatible with some versions of System Software. This is a situation that you can usually identify fairly quickly. Usually crashes and problems develop shortly after you install some new add on software or after you install new version of System Software. Your only recourse is to remove the offending add on software and pursue a long-term solution with the software vendor or author.

### - Desktop Manager "Confusion"

The most telling clue to this problem is when you try to open an application by double-clicking on one of its documents, or in trying to print one of its documents from the desktop, you receive a message that tells you the "application is busy or missing." If this is the case, either your application IS busy (for instance, you are trying to run a single user program on a network when someone else is already running it); it is missing (it is corrupt or you've trashed it inadvertently); or the desktop manager is unable to locate the application.

First, check and make sure the application really is on your drive. Next, launch the application and make sure that it is not corrupted. If the application is not being used by anyone else, it is on your drive, and it does work, then restart your computer while holding down the Option and Command keys.

A dialog box will appear informing you that rebuilding your desktop will take a few minutes, and given the option to continue or abort. Click OK (you can stop holding down the two keys at this point). Your desktop will be rebuilt and you should be able to continue without any problems. It is usually prudent to update desktop periodically.

## Macintosh II: Certificate of Occupancy Information (9/94)

Revised: 9/2/94  
Security: Everyone

Macintosh II: Certificate of Occupancy Information (9/94)

Article Created: 30 August 1989  
Article Reviewed/Updated: 02 September 1994

### TOPIC -----

When furnishing a new office with Macintosh computers, a Certificate of Occupancy is often required. Information needed for this certificate includes:

- EMI (Electro-Mechanical Interference) levels
- Burn test results, meaning what is released when a Macintosh is consumed by fire
- Power and grounding parameters

### DISCUSSION -----

Quite often, the information needed for a Certificate of Occupancy is a certificate of compliance from a governmental or a recognized industrial or other safety committee to ensure that adequate protection exists for users against potential health hazards, such as radiation, electrical shocks, and fire hazards, and from RFI interference to radio and television reception. The Macintosh II computer meets national and international product safety requirements. The Macintosh II is approved by the American (Underwriters Laboratories--UL, and FCC), Canadian (Canadian Standards Association--CSA), and European (Institute for Industrial Research and Standards--IIRS) groups, and so on. The evidence of certification that it may be sold in a particular country is in the form of a label affixed to the bottom of the case.

Apple's grounding requirements are usually within those required by building codes in most communities. We suggest that the "third" wire be grounded for the safety of the operator, so that grounding loops don't build within devices, from which one could obtain an electrical shock.

Apple doesn't perform burn tests but works with the UL, which does, to ensure we are avoiding using materials that could contribute to a fire. This includes PCB material, housing plastic (which contains a fire retardant), and other parts. In general, PCB material is flame rated 94V-1 or better, wire should be

UL-Listed/CSA-Certified VW-1, and plastic parts within the enclosure are flame rated 94V-2 or better. We generally use components that have been certified by the safety agencies. Components include such things as lithium batteries, power relays, tape drives, and so on.

Most plastics do give off toxins when burned; however, as mentioned above, the housings and plastics do contain fire retardants, and are all UL-approved.

For more information see:

- The Macintosh Hardware Family Reference manual, Chapter 23, Macintosh II Power. This chapter goes into the AC input power requirements in detail.

## AppleTalk Internet Router: Doesn't Translate DDP-to-IP (11/94)

Revised: 11/30/94  
Security: Everyone

AppleTalk Internet Router: Doesn't Translate DDP-to-IP (11/94)

=====

Article Created 4 September 1989  
Article Reviewed/Updated: 30 November 1994

QUESTION -----

Is there any way using the Apple Internet Router and the MacTCP drivers to encapsulate an AppleTalk protocol and place it on a TCP/IP-based backbone?

The reason I ask is that I have a customer changing their networking strategies to implement a TCP/IP-backbone only. If you can't play in this environment, they don't want you on the backbone. What the customer wants is to connect their 30 Macintosh networks onto the backbone using TCP/IP. They like the idea of the Internet Router over a Cayman- or Kinetics-type solution.

RESPONSE -----

With the release of the newer Apple Internet Router, TCP/IP tunneling is possible. Also the Apple IP Gateway is a DDP-to-IP gateway. For more information about these products use them as a search string.

The older AppleTalk Internet Router does not provide DDP-to-IP translation. It also does not have the ability to encapsulate AppleTalk packets within IP packets to ship the packets to another router over a backbone. It provides AppleTalk Phase II routing over multiple physical media (Token Ring, Ethernet, and LocalTalk).

MacTCP performs the opposite of what your customer is requesting. When it is on a machine on an AppleTalk network, MacTCP encapsulates TCP/IP packets within AppleTalk packets. It then sends the packets to a DDP-to-IP gateway, which strips the AppleTalk information and sends the TCP/IP packets to the appropriate TCP/IP network device, such as a UNIX system.

The Cayman GatorBox and Kinetics FastPath are examples of the DDP-to-IP gateway mentioned above. They do not encapsulate AppleTalk packets within TCP/IP packets either. Also, when they act as AppleTalk routers, they perform the same types of operations for an AppleTalk Phase I network as the Apple Internet

Router provides for a Phase II network. Note that we are discussing the current versions of these products, which do not yet support AppleTalk Phase II; however, adding Phase II support to these products still would not provide the functionality your customer desires.

For more information, search on "Cayman" or "Kinetics" in the Tech Info library.

## Apple Data Modem 2400: Supports Flash Command

Revised: 9/18/89  
Security: Everyone

Apple Data Modem 2400: Supports "Flash" Command

=====

This article last reviewed: 4 September 1989

TOPIC -----

I have an application that requires approximately a 1/2-second break (sometimes referred to as a 'flash hook' or a 'switch hook') to be generated by the modem. There are a number of modems that provide this feature by sending an exclamation point ('!'). The Apple Personal Modem does not support this.

Does the new Apple Data Modem 2400 support this feature?

DISCUSSION -----

Yes, the Apple Data Modem 2400 does support the 'Flash' command; the character used is the exclamation point ('!'). This command causes the modem to go ON-HOOK for half a second, then go OFF-HOOK. This is a useful command for transferring telephone calls on some telephone systems.

## AppleShare File Server 2.0.x: File Limits and Memory (1/97)

Revised: 1/25/97  
Security: Everyone

AppleShare File Server 2.0.x: File Limits and Memory (1/97)

=====

Article Created: 31 August 1989  
Article Reviewed/Updated: 25 January 1997

TOPIC -----

Are there any limits imposed by AppleShare File Server as far as the following parameters are concerned?

- 1) Total number of files per volume.
- 2) Total number of files in a folder.
- 3) Total number of files on the file server.
- 4) Total number of open files.
- 5) The memory used by open and closed files?

Is it possible that a large number of files can cause memory problems on AppleShare File Servers?

DISCUSSION -----

AppleShare does not impose any additional limits that HFS does not. HFS and AppleShare allow the following:

1) Total number of files per volume.  
A count of the total number of files and directories on the volume is maintained, as a LongInt, in the master directory block (block 2). Directory IDs are also LongInts. This limits the number of files and folders on the volume to  $2^{32}-1$  (roughly 4.3 billion). That many folders could be created as long as there's room on the volume to hold the expanding catalog B\*-Tree. Because each file occupies at least one allocation block, all of the, at most, 65,536 allocation blocks (also numbered by Integers) will be allocated just before that many files are written on the volume. 65,536 is the maximum number of files on an HFS volume.

2) Total number of files in a folder.  
There is another limitation imposed: a directory's valence is an Integer, and,

furthermore, on GetCatInfo requests, any negative number in the ioFlIndex field is interpreted as a request for information on the directory itself. So, while HFS allows the creation of up to 65,536 files in each directory, all of which can be accessed by name, only 32,767 can be enumerated--a real limitation on folder contents. In practice, the user's patience will run out well before this many items can be enumerated.

3) Total number of files on the file server.

The maximum number of files on a file server vary depending on the version of AppleShare you use.

AppleShare 2.0.x allows 16 volumes

$$16 \times 65,536 = 1,048,576$$

AppleShare 3.0.x and later allows 50 volumes

$$50 \times 65,536 = 3,276,800$$

4) Total number of open files.

If the server is equipped with 1MB, the default maximum number of files that can be opened is 80. If you increase the server's RAM to 2MB, the default maximum number of files that can be opened also increases to 160.

The number of FCBs is pointed at by the value in \$34E (hex). The number of FCBs is indicated in the first word in that table. On a 1MB machine, the default value is \$1D62; on a 2MB server, the value is \$3AC2. There is a one-to-one relationship between the File Control Blocks and the number of individual files you can have opened; that is, each file uses one FCB.

An easy solution to problems involving "too many files" is to increase the amount of RAM. If you increase the FCB, you, potentially, would subject your server to system errors, possibly at times when you are maximizing RAM usage.

With servers now having more RAM, there are maximum limits for open files. They are as follows:

|                       |        |
|-----------------------|--------|
| AppleShare Pro        | 5000   |
| AppleShare 4.2.x      | 3000 * |
| AppleShare 4.x        | 346    |
| AppleShare 3.x        | 346    |
| AppleShare 2.0.1      | 160    |
| Personal File Sharing | 346    |

\* 3000 instances of 346 unique files.

5) The memory used by open and closed files?

Closed files use no RAM space at all. Just opening a file uses no memory either, but it does take an FCB. Loading the resources into memory uses more memory, and how much depends on the particular files.

And finally, no, an AppleShare File Server is not encumbered by a volume or volumes with a large number of files because it does not cache any of the file directory information.

Security: Everyone

LaserWriter Driver 6.0: Compatibility Issues

=====

Article Created: 31 August 1989  
Article Last Reviewed: 31 October 1991  
Article Last Updated: 31 October 1991

TOPIC -----

I have three questions about the LaserWriter 6.0 driver in a mixed AppleTalk environment.

- 1) Are there compatibility issues among LaserWriter, LaserWriter Plus, LaserWriter IINT, and LaserWriter IINTX printers?
- 2) How does the page format for #10 envelopes work with the software (that is, do the margins automatically adjust)? I assume that one should not choose this option if working with older LaserWriter products that do not have center feed.
- 3) Because installation of LaserWriter 6.0 requires System 6.0.3, is there a system problem when running on Macintosh Plus, and earlier computers?

DISCUSSION -----

- 1) The LaserWriter 6.0 drivers are compatible with the LaserWriter, LaserWriter Plus, LaserWriter IINT, and LaserWriter IINTX printers.
- 2) The page format information is retrievable by the application from the printer driver. Not all applications adjust their page formats based on this information. The #10 envelope setting is intended for the LaserWriter II family of printers and their center-feed mechanism.
- 3) The LaserWriter 6.0 drivers require System Software 6.0 or later. This means that the Macintosh Plus and later support the LaserWriter 6.0 drivers. The Macintosh 512e and earlier computers do not. Note: The LaserWriter 6.0 drivers use the Notification Manager, which is available only in System Software 6.0 and later.

## Macintosh Plus: Dual-Voltage Switch (4/93)

Revised: 4/8/93  
Security: Everyone

Macintosh Plus: Dual-Voltage Switch (4/93)

Article Created: 31 August 1989

### Article Change History

04/07/93 - REVISED

- Separated unrelated information into another article.

### TOPIC -----

The Macintosh Family Hardware Reference (Addison-Wesley) states at the end of the Macintosh Plus section that all late model Macintosh Plus systems have a dual-voltage 50/60 Hz 110-120/220-240VAC power supply that comes preset to 110-120VAC but can be changed to the higher voltage via a switch on the analog board. I can't find it the switch. Is this a publication error, or is the switch really there?

### DISCUSSION -----

Only international versions of the Macintosh Plus ship with the dual-voltage 50/60 Hz 110-120/220-240VAC power supplies. The domestic version of the Macintosh Plus system ships with the 50/60 Hz 110-120VAC power supply.

The information to which you are referring is on page 7-2 of the Macintosh Family Hardware Reference and is incorrect.

## Macintosh SE, SE/30: Possible Combinations of Internal Drives

Revised: 8/7/92  
Security: Everyone

Macintosh SE, SE/30: Possible Combinations of Internal Drives

=====

Article Created: 18 September 1989  
Article Last Reviewed: 7 August 1992  
Article Last Updated: 22 August 1991

TOPIC -----

What are the possible combinations for the internal drives on a Macintosh SE and SE/30?

DISCUSSION -----

The Macintosh SE chassis is capable of holding two 3.5-inch storage devices. The Macintosh SE and Macintosh SE/30 logic boards use the same amount of space in the Macintosh SE chassis. The Macintosh SE/30 logic board has only one internal floppy-drive connector. Based on this information, it is possible to have these combinations of hardware installed in the Macintosh SE chassis:

- 1) Macintosh SE logic board; one 800K floppy drive.
- 2) Macintosh SE logic board; one Apple SuperDrive (formerly Apple FDHD).
- 3) Macintosh SE logic board; two 800K floppy drives.
- 4) Macintosh SE logic board; two Apple SuperDrives.
- 5) Macintosh SE logic board; one 800K floppy drive, one 3.5-inch hard drive.
- 6) Macintosh SE logic board; one Apple SuperDrive, one 3.5-inch hard drive.
- 7) Macintosh SE/30 logic board; one 800K floppy drive.
- 8) Macintosh SE/30 logic board; one 800K floppy drive, one 3.5-inch hard

drive.

9) Macintosh SE/30 logic board; one Apple SuperDrive.

10) Macintosh SE/30 logic board; one Apple SuperDrive, one 3.5-inch hard drive.

## MacDraw II 1.0: Does Not Curently Support Color QuickDraw

Revised: 9/18/89  
Security: Everyone

MacDraw II 1.0: Does Not Curently Support Color QuickDraw

=====

This article last reviewed: 31 August 1989

TOPIC -----

I am using both PixelPaint and MacDraw. When I copy and paste from PixelPaint into MacDraw, I lose the color I have painstakingly put into the graphics.

Do you have any suggestions on a cause and remedy?

DISCUSSION -----

MacDraw and MacDraw II do not support Color QuickDraw. MacDraw II displays the eight colors that the original QuickDraw supported. This is why the color information from a PixelPaint object(s) is lost when pasted into MacDraw II.

Another problem is that PixelPaint allows you to modify the palette of colors being used. If the system palette is not used, the colors may change when pasted into another application.

## AppleShare PC: How To Change the Printer Timeout Parameter

Revised: 9/18/89  
Security: Everyone

AppleShare PC: How To Change the Printer Timeout Parameter

=====

This article last reviewed: 31 August 1989

TOPIC -----

I am trying to permanently change the printer timeout parameter in AppleShare PC 1.x. I can change the parameter, but whenever the machine is restarted, the parameter is reset to default.

DISCUSSION -----

The printer timeout parameter should stay as set even if the machine is restarted. We tested this on an IBM-XT running AppleShare PC 1.2.

Make sure that you reply "Yes" to the question:

Connect automatically at startup?

in the LaserWriter Connect window.

Another way to ensure that the timeout parameter stays after restart is to use the ANET command CONNECT in the PC AUTOEXEC.BAT file. Example:

```
ANET CONNECT LPT1: N(Printer Name) P(LaserWriter) D(timeout)
```

Please refer to the AppleTalk PC Update of the AppleTalk PC Printer Driver, part no 031-1031-A, for more information.

## MacDFT: Compatibility with Other Communications Products

Revised: 9/22/89  
Security: Everyone

MacDFT: Compatibility with Other Communications Products

=====

This article last reviewed: 31 August 1989

TOPIC -----

How does a Macintosh on Token Ring appear to NetView? Will NetView see Macintoshes attached to the Token Ring via LocalTalk or Ethernet using our Internet Router?

Will Apple's first release of MacDFT, which supports DFT over Token Ring from a 3174 controller, allow mainframe sessions to be distributed to Macintoshes over LocalTalk and/or Ethernet?

Likewise, will Apple's first release of MacDFT, which supports DFT, allow sessions to be distributed from our coax card to Macintoshes on LocalTalk and/or Ethernet?

DISCUSSION -----

Apple Computer's TokenTalk product conforms to the 802.5 Token Ring standard of the Medium Access Control (Macintosh) layer as defined by IEEE 802 Local Area Network Committee. A Macintosh with the TokenTalk NB Card appears to NetView as a Token Ring node, but it does not support NetView diagnostic functions because these NetView functions are not implemented in AppleTalk.

NetView does not see Macintoshes attached to the Token Ring via LocalTalk or Ethernet through the Internet Router because the Internet Router was not developed to support NetView and, therefore, does not pass LocalTalk and EtherTalk node information to NetView.

The first release of MacDFT, which supports DFT on coax or Token Ring cards, does not support distributions of mainframe sessions over LocalTalk or EtherTalk.

## Electronics Data Interchange (EDI): General Description (9/94)

Revised: 9/8/94  
Security: Everyone

Electronics Data Interchange (EDI): General Description (9/94)

=====

Article Created: 5 April 1990  
Article Reviewed/Updated: 8 September 1994

TOPIC -----

This article provides a general description of Electronics Data Interchange (EDI).

DISCUSSION -----

EDI stands for Electronics Data Interchange. Officially, it is Electronics Business Data Interchange (EBDI), but the "Business" part of the title is often left out. EDI refers specifically to the exchange of business data. It defines the format and data content of business documents, like purchase orders, so that both the buyer's and seller's computers can process them, typically, at an enormous savings in data entry costs.

There are currently two EDI standards-setting groups in the United States: the TDCC and ANSI X.12 Committee. The worldwide standard-setting body for EDI is EDIFACT (part of ISO); EDIFACT standards are just beginning to be developed but are moving quickly. EDIFACT and ANSI are working toward compatibility.

TDCC, a transportation industry standards group, originally began developing EDI standards and then asked ANSI to endorse standards for all industries. TDCC and ANSI use a common data element dictionary, but they build their transaction sets differently.

Industries, other than transportation, use the ANSI standard. The standard is very large and general because it has to meet the needs of all businesses in the USA. Specific industry groups, such as EIDX for the electronics industry, use the ANSI standards but decide which optional segments and elements are used for each transaction set. Also, the industry groups select which table values to use. For example, ANSI has several hundred unit of measure values that may overlay, such as each, piece, box, set, unit, and so on. EIDX has adopted each as the only unit of measure the electronics industry needs. These industry groups simplify exchange within the industry.

The structure of an EDI message is:

- 1) Transaction Set is equivalent to a business document, such as a purchase order. Each transaction set is made up of data segments. Transaction sets are listed in Transactions Set Tables.
- 2) Data Segments are logical groups of data elements that together convey information, such as invoice terms, shipping information, or purchase order line. Data Segments are listed in the Data Segment Directory.
- 3) Data Elements are individual fields, such as purchase order number, quantity on order, unit price, and so on. Data Elements are listed in the Data Element Directory.

## A/UX: Block-to-inode Mapping

Revised: 9/30/92  
Security: Everyone

A/UX: Block-to-inode Mapping

=====

Article Created: 31 August 1989

### Article Change History

-----

08/31/92 - REVIEWED

- For technical accuracy.

### TOPIC -----

I am having some problems with a bad block on the disk. I want to 'badblk' it, but I also want to save the file (inode) that used the block to another file before doing that.

I noticed that there is no utility in A/UX 1.1 that does a block-to inode mapping. In SysV systems you usually find icheck, which does this kind of stuff. Did I misread the manuals, or is there no facility to backtrace the blocks to the originated inode? Can I port the icheck to the next release of A/UX?

Another issue with badblk is the so-called "hardware sparing". This is mapped to a ioctl(fd,GD\_SPARE),block) inside badblk, which is then translated to a SCSI call in our device driver. I'm using Rodime drives, so I really don't know the hardware-specific way of doing the hardware sparing. I am curious to know how Apple's disks do this. Does Apple support this hardware sparing with our disks? (One could speculate that the disk device copies the block information to another pure block, changes some kind of internal pointer table, and maps the bad block to a bad block table.)

### DISCUSSION -----

We, too, noticed that the 'icheck' utility (block number to i-node number mapping) is not included in A/UX 1.1. The porting of 'icheck' utility has not been implemented.

We don't know how well the Rodime hard disk supports the "hardware sparing" either. However, we believe that the Apple HD80 SC (Quantum Q280) drives are intelligent disk drives and capable of "hardware sparing" support; it incorporates media defect handling and error correcting code capabilities. During regular disk operation, the drive can continue to scan and compensate for any new defective sectors that may show up later on the disks.

On the software side of the bad-blocking (the 'badblk'-set or update bad block information), we have the following test, and it seems to work.

```
# badblk /dev/rdisk/c0d0s31
==> badblk:  block #33988 was not bad blocked
==> badblk:  block #33999 was not bad blocked
==> no blocks bad blocked
```

```
# badblk /dev/rdisk/c0d0s31 33988 33999
==> 2 blocks spared, 0 blocks altblked
```

```
# badblk /dev/rdisk/c0d0s31
==> no blocks bad blocked
```

According to the description of 'badblk', badblk first attempts to alter a bad block by hardware sparing. If the hardware sparing fails and the device supports alternate bad blocking, badblk attempts to alternate block the bad block.

Note that for the space-saving reasons, the current A/UX distribution disk partitions do not have the alternate block area reserved for bad block handling. If the bad sectors occur, it will be done by the hardware sparing.

## AppleShare 2.0.1: Adding or Copying Drop Boxes (5/95)

Revised: 5/25/94  
Security: Everyone

AppleShare 2.0.1: Adding or Copying Drop Boxes (5/95)

=====

Article Created: 31 August 1989  
Article Reviewed/Updated: 25 May 1994

TOPIC -----

I am running AppleShare 2.0.1 on a Macintosh II and am having trouble with the drop boxes. I have installed two new 140MB hard drives on my AppleShare File Servers; each is treated as an additional "volume". There is no trouble accessing either of the new volumes or placing folders and documents on them. The trouble is that drop boxes do not appear as drop boxes. For example, some drop boxes were copied from the original volume to the new one, and the arrow no longer appears--the drop box is essentially another folder. When new folders are added, and someone goes to Access Privileges and creates a drop box, the same thing happens. Correcting this problem is very important due to security.

DISCUSSION -----

We do not have any difficulty creating drop boxes under this version of AppleShare. When you copy a folder from one AppleShare volume to another, one of two things happens: If you set the copy inherit bit in the LAYO resource in the Finder to on, the copied folder "inherits" the privileges of the directory it is being copied to. Or, if this bit is not set, the folder being copied has the default settings with access completely restricted to the owner of the folder (you). Either way, the privileges are being changed from the settings of the originating folder.

Also, ensure that whoever owns the drop box is not the one logged on. If it is, this person will not see the folder as a drop box; rather as an owned folder. Check the privileges on the folder after you change them to those of a drop box.

If the settings are reported correctly, have a nonowner try to open the folder and copy files. The nonowner clearly should not be able to. If it can, then have that account check the folder's privileges.

Another possible cause of the problem may be the 140MB hard drives being used. Since we tested this using standard Apple hard disk drives, it is possible that the hard drives are the difference between our configuration and yours. We

would suggest checking with the manufacturer of your drive to verify that it doesn't have problems working with AppleShare 2.0.1.

## AppleTalk: Wide-Area Networking Issues Using Satellite Links

Revised: 9/22/89  
Security: Everyone

AppleTalk: Wide-Area Networking Issues Using Satellite Links

=====

This article last reviewed: 31 August 1989

TOPIC -----

I am working toward extending our AppleTalk network from Plano, Texas, to various other offices (such as, specifically, Anchorage via 56Kb phone links for Ethernet). This 'extended' Ethernet is primarily being done to support some VAX systems, but AppleTalk packets get out over the TransLan bridges anyway, so AppleTalk goes 'piggyback' on the Ethernet with no particular trouble.

So far, Plano and downtown Dallas are connected. There is Liaison and FastPaths on the Plano end and Liaison in Dallas. AppleShare servers and printers and zones show up fine, although response time is a bit slow.

In a few weeks, I hope to have Anchorage on-line via telephone satellite. I have been trying to get some idea of how bad the delay caused by the satellite phone link will be.

Are any software packages that make use of the ADSP protocol (which sounds to me like what we really need for eliminating the wait for every packet's response)?. For instance, I've heard that CE's newest QuickMail product does this. Based on the times involved, my estimate is that the time delay due to the 24,000 mile distance to the satellite will be slightly better than that seen with a Liaison remote phone link with a 9600-baud modem.

Is this reasonable, or is there some other problem I don't know about? Will AppleShare tolerate these time delays?

DISCUSSION -----

A satellite link will add approximately a quarter-second delay between the time a packet is transmitted at one end of the link until the time it is received at the other end of the link. This propagation delay is about 15 times greater than that seen in a 3000-mile ground link, which approaches a fiftieth of a

second. This assumes perfectly clean channels; when you include error rates, ground-based analog lines have greater error rates than satellites, which require more retransmissions.

The quarter-second delay would be most noticeable in the case of extremely bursty types of communications. The best example of this type of communication is a full-duplex character mode terminal session. If the character typed at the terminal has to be echoed by the remote host before it is displayed on the screen, you see a one-half-second delay between the time a character was typed and the time it was displayed on the screen.

At the other end of the spectrum is the completely one-way transmission of large amounts of data. The quarter-second delay caused by the satellite link would then become virtually unnoticeable.

Reality will fall somewhere between these two scenarios. Typically, the amount of data transmitted in each AppleTalk packet will be in the hundreds of bytes. Also, constant send/receive-style communication is greatly reduced. For instance, communication between a Macintosh and a LaserWriter follows the pattern of 8 data packets being sent by the Macintosh, followed by a request for the next set of 8 sent back by the LaserWriter. This transaction-based communications is at the heart of most AppleTalk traffic.

AppleShare servers and LaserWriters communicate via the AppleTalk Transaction Protocol (ATP), which implements these communications along with guaranteed packet delivery. Using files servers and printers over this long distance link, as if they were locally attached, is not a recommended solution. However, we have seen these types of operations work reliably at speeds as low as 1200 baud via asynchronous links, so communications via the satellite link should work.

Problems that slower speed links cause often are caused by errors on the network. Satellite links themselves are very reliable, but if one of the ends of the link is having network errors, continual retransmission requests across the link, due to packets lost on the misbehaving side, will cause problems. This makes it doubly important that the quality of the networks on both sides be doubly checked and well within the recommended limits of cable lengths and nodes per network.

Also, in AppleTalk Phase 1, there is no best router algorithms in use, so sometimes a Macintosh will use a router on the other side of a slow link as its router to devices on its side of the link. This is a problem only with Macintoshes directly connected (via Ethernet cards, and so on) to the backbone that includes the long distance link, and it can cause significant delays. AppleTalk Phase 2 addresses this problem, and your customer should seriously consider upgrading to Phase 2.

To address the ADSP question above, ADSP is typically used for data-stream-type communications over a network. The classic example of this is terminal services over a network. ADSP was implemented to try to reduce the impact of the problems posed by the character-by-character nature of these transactions. We do not see a need to look for other network applications that specifically use ADSP unless you are looking at the possibility of terminal services across

the remote link, such as logging on to a VAX via PacerLink.

It is important to realize that the actual throughput and user-perceived throughput will vary on a case-by-case basis. As the backbone traffic increases, causing more delays due to nodes waiting to send, the actual delay from the satellite link will become a smaller and smaller portion of the overall delays on the network. If network services are configured to take the link into account, perceived throughput will be even greater. For instance, electronic mail services could be configured so that messages sent across the link were only sent twice a day at low-activity periods.

As a final note, the issues discussed above are mostly not AppleTalk- specific. Adding satellite links to any networking schemes magnifies the complexity of that network by an order of magnitude. This is definitely not a plug-and-play operation (not yet, anyway), but it has been successfully implemented within the AppleTalk world, and much more often in the TCP/IP world.

## AppleTalk Phase 2: Questions and Answers (11/94)

Revised: 11/14/94  
Security: Everyone

AppleTalk Phase 2: Questions and Answers (11/94)

Article Created: 22 September 1989  
Article Reviewed/Updated: 14 November 1994

TOPIC -----

The announcement of AppleTalk Phase 2 has been both a delight and yet scary to some of our customers with large (>2500 Macintoshes) and varied AppleTalk networks (LocalTalk and Ethernet). I have not seen a good document describing upgrade procedures. Is there one that you know of? If not, here are some unclear areas of concern that I need answered:

- 1) Does the Upgrade Utility of the AppleTalk Internet Router software handle the compatibility between Phase 1 and Phase 2 nodes connected to the same Ethernet, or am I going to have a compatibility problem between EtherTalk 1.x and 2.0?
- 2) If so, can I put a single AppleTalk Internet Router with the Upgrade Utility on Ethernet to handle the compatibility between Phase 1 and Phase 2 nodes throughout the entire network (some Macintoshes are on the Ethernet, and some are on LocalTalk networks bridged with Kinetics FastPaths)? Or, will a Router be needed at each LocalTalk-to-Ethernet junction?
- 3) Will AppleTalk Phase 2 require a particular level of Macintosh OS; that is, will there be any problem having Macintoshes with 5.x/AppleTalk Phase 2 and Macintoshes with 6.x/AppleTalk Phase 2?
- 4) Will an upgrade to AppleShare be required?

RESPONSE -----

- 1) The Upgrade Utility was specifically designed to allow both AppleTalk Phase 2 and AppleTalk Phase 1 to work together on the same network.
- 2) If you have a Phase 1 router connected to a LocalTalk network, every Phase 2 router that needs to communicate with the Phase 1 router must

run the Upgrade Utility. If you have a Phase 1 router connected to an Ethernet, it is possible to have only one Phase 2 router connected to the Ethernet running the Upgrade Utility. A manual will be provided with the Upgrade Utility specifying in greater detail the possible configurations and which routers need to run the Upgrade Utility. Also, see the binders associated with the LAN Minds training for more information.

- 3) TokenTalk, EtherTalk 2.0, and the Apple Internet Router have been tested only with System 6.0.3, so devices specifically running AppleTalk Phase 2 products must run System 6.0.3. Other devices should be able to run older versions of the System software without any ill effects.
- 4) AppleShare will not require an upgrade to work with AppleTalk Phase 2. AppleTalk Phase 2 should only affect bridge, router, and gateway products. The upgrade should be transparent to network services, such as file servers and printers.

## Macintosh II: Problems Adjusting the Color with 4-bit Video

Revised: 9/22/89  
Security: Everyone

Macintosh II: Problems Adjusting the Color with 4-bit Video

=====

This article last reviewed: 31 August 1989

TOPIC -----

Sometimes the color selection works fine, and sometimes it does not. It seems to work OK on the primary colors along the outer rim of the color wheel. However, when I move in toward the center, choose a color, say OK, I get a completely different color than what I chose. Sometimes the color does not change at all--it stays a dark gray.

Another problem is that when you change the color successfully and restart, the color returns to the color before the change! I tried this on an 8-bit video card system, and it worked fine. So, at this point, it seems to be a problem with 4-bit video systems. This is the first color problem I have encountered, but it is easy to duplicate on a 4-bit video system by going into the "color" option in the Control Panel and making various changes to the default color. I am running System 6.0.3.

Is there a workaround for this, or is this a problem being addressed by a new update for the operating system?

DISCUSSION -----

The situation you are describing is a direct result of the number of colors that can be displayed on a screen at one time. With a 4-bit video card, this number of colors is a total of 16 at any one time.

The Color Picker will display any one of the 16.7 million colors that Color QuickDraw is capable of generating. It does this by altering its color lookup table on the fly as you request different colors. When you click the OK button, the values chosen are returned to the calling program (in this case the Color Control Panel Device). The program then uses this value; the Color CDEV uses it to set the color of text selections. However, the way this color actually is displayed depends on the current color lookup table (CLUT) in use, which has no bearing on what was being used in the Color Picker Package. In

most cases, the CLUT being used is the standard system CLUT. The color chosen in the Color Picker is mapped to the closest available color in the system CLUT, and that color is the one that you actually see on the screen.

When you only have 16 colors available on the screen at one time, it is likely that you will not get the color displayed in the Color Picker, and, quite often, you see the exact same color you had on the screen before--even though the actual RGB values specified are very different. This same sequence of events occurs with an 8-bit video card. The difference is that with 256 colors on the screen at one time, you have more colors to map to in the system CLUT, and it seems as though you are getting the actual values requested.

## Macintosh-to-Data General Connectivity

Revised: 9/22/89  
Security: Everyone

Macintosh-to-Data General Connectivity

=====

This article last reviewed: 31 August 1989

TOPIC -----

Is it possible to connect a Macintosh through Ethernet to a Data General computer?

DISCUSSION -----

The method of connection will depend on the operating system and network protocols supported on the Data General machine. If you are running UNIX on the Data General, then the standard TCP/IP connectivity solutions should work. These would include terminal emulation and file transfer programs, such as NCSA Telnet.

If you are running the proprietary Data General operating system, then being able to connect will depend on the protocols supported by that operating system. Once again, it is possible that the operating system will support TCP/IP, at which point you would be able to connect over the Ethernet. It is also possible that the Data General would support another set of protocols we can connect to, but TCP/IP is most likely.

If neither of the above options is available, you will be restricted to serial connections using a terminal emulation package, such as MacTerminal.

## DAL and TCP/IP in VM Environments (12/94)

Revised: 12/5/94  
Security: Everyone

DAL and TCP/IP in VM Environments (12/94)

=====

Article Created: 22 September 1989  
Article Reviewed/Updated: 05 December 1994

TOPIC -----

I have a question concerning Data Access Language (DAL) and TCP/IP. With the DAL for VM solution, I normally would have a 3278 emulation terminal with a coax connection to the cluster controller-FEP-host.

If on the 802.3 backbone we had IBM mainframes and access to them via TN3278 (either NCSA's or Intercon's product), would DAL in the Macintosh connected via LocalTalk to a FastPath 4 or GatorBox work in this case? The IBM host would have to be running all of the proper software, and again, the 802.3 cable can only have IP packets on it.

DISCUSSION -----

Dal supports TCP/IP access via Mac TCP to a VM DAL server as of release 1.3.

AppleShare: UNIX Compatible Development Encouraged

=====

This article last reviewed: 7 September 1989

TOPIC -----

Does Appple want people to develop AppleShare-compatible file servers for other platforms?

I am working with a local mini-super manufacturer running a variant of UNIX and they are very interested in bundling some Macintosh system services with their package.

Can you guide me to the proper resources?

DISCUSSION -----

Apple actively encourages people to develop AFP-compatible file servers. You also should inform them of the existing products that turn UNIX systems into AppleShare servers, such as Columbia AppleTalk Package (CAP) from Columbia University and uShare from Information Presentation Technologies. Search on the above names in Tech Info library for more details on these products.

You should advise your mini-super computer manufacturer to contact Apple Developer Services Hot Lines at 408-974-4897 to get more information about developing AFP-compatible file servers. Contact Software Licensing at 408-974-4667 for information about bundling Macintosh System software with their package.

## MacTCP: TCP/IP Ethernet and AppleTalk Compatibility

Revised: 9/22/89  
Security: Everyone

MacTCP: TCP/IP Ethernet and AppleTalk Compatibility

=====

This article last reviewed: 7 September 1989

TOPIC -----

Here is a question about Macintosh-to-Cray connectivity and AppleTalk Phase 2 products. Will the GatorBox and Kinetics boxes be able to communicate using TCP/IP?

Also, will I be able to use MacTCP with Apple's EtherTalk NB Card and VersaTerm Pro?

DISCUSSION -----

The Kinetics FastPath and the GatorBox are both Datagram Delivery Protocol-Internet Protocol (DDP-IP) gateways. Both perform the same function of taking a TCP/IP packet that is encapsulated in DDP and AppleTalk protocol, and converting it to Ethernet format from LocalTalk. DDP-IP gateways also can assign addresses to MacTCP nodes and handle routing to other networks. PacerLink software from Pacer Software, Inc. can be used in this situation to emulate VT100 terminal with softkeys. VersaTerm Pro terminal emulation software does similar functions and can be used as well.

MacTCP runs over both Ethernet- and LocalTalk-compatible cabling systems. If you run MacTCP on LocalTalk cable, you need a DDP-IP gateway, like the FastPath or the GatorBox. By default, the DDP-IP gateway should be located in the same AppleTalk zone as the Macintosh computer running MacTCP. Alternatively, a single DDP-IP gateway can support Macintosh computers in multiple AppleTalk zones; in this case, the zone where the DDP-IP gateway resides must be selected by the user using the MacTCP Control Panel.

If you run MacTCP over Ethernet using our Ethernet NB Card, you do not need a DDP-IP gateway. You do not need PacerLink or VersaTerm Pro. To provide remote terminal service, you need software, like NCSA Telnet or Internet Systems Corporation (also known as Intercon) TCP/Connect. Both of these software packages provide terminal emulation and file transfer protocol.

## Macintosh Finder: Trash Can and Directory Changes

Revised: 7/19/91  
Security: Everyone

Macintosh Finder: Trash Can and Directory Changes

=====

Article Created: 7 September 1989  
Article Last Reviewed: 2 February 1991  
Article Last Updated:

TOPIC -----

Why can I open an application in MultiFinder, then drag documents into the Trash, yet still be able to open these same documents from the launched application?

Conversely, when I open a document put into the Trash directly from the Finder, the following error message appears: "Please drag the item out of the Trash."

DISCUSSION -----

What you are experiencing is not a bug. The reason you can open a "deleted" document is that applications can still see the directory entry for a document that you have put it in the Trash, but not emptied. The Finder empties the Trash when an application launches.

In your case, you launched your application before dragging the document into the Trash, so the file still had an entry in the directory. On the other hand, the Finder knows when you are trying to open a file from the Trash and displays an error message saying that you should not do so.

## Macintosh-to-Amdahl Connectivity

Revised: 9/22/89  
Security: Everyone

Macintosh-to-Amdahl Connectivity

=====

This article last reviewed: 7 September 1989

TOPIC -----

Do you have any information on Amdahl mainframes running the operating system TCAM? I need to connect a 10-node Macintosh network to an Amdahl mainframe, model 5890. I want the mainframe to be able to access the network. Should I connect each Macintosh via an IRMA board to the mainframe?

Also, will the MacDFT product and the Coax/Twinax Card allow a network or only a single workstation to access to the mainframe?

DISCUSSION -----

TCAM is not an operating system. It is an access method like BTAM and VTAM. Amdahl mainframes either run an IBM operating system, such as VM, MVS, or DOS, or their UNIX operating system UTS.

Since you are doing terminal emulation, the operating system and access method are not as important to know as the environment they are in; that is, SNA or bisynchronous. Because SNA only runs VTAM and you have mentioned TCAM, we assume that the environment is bisynchronous.

The IRMA board allows single workstation connection (CUT mode). There are versions for the Macintosh SE, Macintosh SE/30, and Macintosh II. They work in both SNA and bisynchronous environments. Use this approach if you are running bisynchronous, or if you are running SNA but do not have any Macintosh IIs. Avatar's MacMainFrame products are equivalent to IRMA boards and can be used as well.

The first version of MacDFT, which will ship with the Apple Coax/Twinax Card, can operate as a CUT mode terminal with one session per Macintosh. A later version will implement a DFT mode terminal with up to five sessions per Macintosh. There are versions for Macintosh II, and stated support is for SNA and non-SNA (channel attached) only. However, if the users are running in

single-session (CUT) mode, they can use MacDFT version 1.0 or 1.1, whether it is SNA, non-SNA, or bisynchronous.

MacDFT only allows single workstation access to the mainframe. For network access, you will be able to use a Macintosh II running MacAPPC with a Serial NB Card, when that product is shipped. If your need is immediate, you'll need an IRMA board or MacDFT with Coax/Twinax Card from each Macintosh to a cluster controller, or to check into the gateway product by Tri-Data Systems.

For more information, search on "Avatar Technology" and "Tri-Data Systems" in the Tech Info library.

## Macintosh-to-MS-DOS Connectivity: AFE and SuperDrive Problems

Revised: 8/23/91  
Security: Everyone

Macintosh-to-MS-DOS Connectivity: AFE and SuperDrive Problems

=====

Article Created: 22 September 1989  
Article Last Reviewed: 22 August 1991  
Article Last Updated: 22 August 1991

### TOPIC -----

Some questions on Macintosh-to-MS-DOS connectivity:

- 1) Users of PS/2 systems routinely format double-sided, double-density disks as 1.44MB (high-density). Apple File Exchange won't mount these disks. Is this a hardware limitation, or could a software patch be issued?
- 2) When storing Microsoft Word 5.0 for the PC documents on an AppleShare File Server (using AppleShare PC 1.2), I have not been able to get Microsoft Word 3.01 or 4.0 on the Macintosh to open the files. AFE routinely does an incorrect WordPerfect translation of these documents.
- 3) Excel 2.x on the PC and Macintosh seems to use the same file format, so that using AFE with default translation easily converts documents from the disk. Is there a simple way to move from Microsoft Word 5.0 on the PC and Word 3.01 or 4.0 on the Macintosh, which preserves style sheets?

### DISCUSSION -----

High-density disks are physically different and tested to a different specification than double-density disks. The high-density disks have a special, thin recording surface that allows the higher data rates used in MFM (Modified Frequency Modulation). The 800K or 400K disk may not be sensitive enough to properly pick up and align the magnetic particles when the Apple SuperDrive (formerly Apple FDHD) writes in MFM. This could cause corruption of the stored data and may result in errors. The SuperDrive looks for the additional "bonus hole" in the upper left-hand corner of the disk. If the hole is not there, the drive will not recognize the MS-DOS disk as a high-density disk. It is not a hardware limitation. This practice is unreliable,

unsupported, and not suggested. For more information, use keyword "SuperDive" to search the Tech Info Library.

We do not have Microsoft Word 5.0 on PC to test the conversion. We are not sure why you mentioned WordPerfect translation in your question either. Microsoft told us that Word on the Macintosh should be able to directly read the document and do the translation. Here are a couple things you might want to try:

- 1) In Word 4.0, see if you can read your MS-DOS document this way: Hold down the Shift key while going into "File" to open the file. "Open" will change to "Open any file".
- 2) Make sure you use the latest and correct AFE translator file. The DCA-RTF/Microsoft Word translator file is on the Microsoft Word Utilities 1 Disk.

Because of the differences in the program on MS-DOS and Macintosh, features such as outlining levels, styles, and tables may not be transferable.

## MacDFT: Terminal Session Limits & Foreign Language Support

Revised: 9/22/89  
Security: Everyone

MacDFT: Terminal Session Limits & Foreign Language Support

=====

This article last reviewed: 7 September 1989

MacDFT supports up to five 3270 terminal sessions per Macintosh using either the Coax/Twinax Card or TokenTalk NB Card. There is no such distinction between host sessions and terminal sessions. The IBM PC 3270, which first used DFT, was designed to support four terminal sessions and one 3287 printer session. Since MacDFT does not support 3287 printing, all five sessions are used for terminal sessions. You do, however, need a 3X74 controller customized to have up to five LUs assigned to the physical coax in use. The LU numbers assigned have to be included in the NCP gen and have to be active or vary'd on by the host operator. The same sort of issues are involved with the Token Ring implementation.

Non-English character set support is part of the product design and is located under the Config Menu labelled Country. Currently, it lists English and Italian. If you need to support foreign language sets, a ResEdit of the ASCII-to-Device Buffer Code table is required within the application.

## Virtual Network: Apple's Definition

Revised: 9/22/89  
Security: Everyone

Virtual Network: Apple's Definition

=====

This article last reviewed: 7 September 1989

TOPIC -----

How does Apple define the term virtual network?

I have heard virtual network defined as the entire Internet; that is, encompassing all networks attached to the physical cable. However, I understood the term virtual network to mean an individual network, which is, in turn, attached to the Internet. Do you know if one definition is an industry standard and the other an Apple definition?

DISCUSSION -----

From our research, there is no industry standard definition for the term "virtual network".

In AppleTalk Phase 2, a physical network can have a range of network numbers associated with it. Each of these network numbers is assigned to a virtual network. A node on this extended network would dynamically choose its network number from the range. What this means is that users can use the virtual network numbers to have more than 253 nodes on a large physical network without having to break up their large physical networks into cables with fewer nodes on them.

We are not sure about your first definition. It sounds like a definition for a "logical network" that encompasses all entities that make up the entire network, regardless of protocols or physical cabling.

For more information, please refer to the Technical Details of AppleTalk Phase 2 section in the LAN Minds training binders.

## A/UX: Powering Down without Root Permission (6/93)

Revised: 8/12/93  
Security: Everyone

A/UX: Powering Down without Root Permission (6/93)

Article Created: 7 September 1989  
Article Reviewed/Updated: 24 June 1993

TOPIC -----

I want to be able to restart or power down in A/UX when I'm not the SU  
(super user):

```
chmod 7777 /etc/powerdown  
chown user /etc/powerdown
```

This doesn't seem to work: Do you have any ideas?

I understand some of the implications like shutting down processes, but  
shouldn't one be able to simulate this as a user?

DISCUSSION -----

The reason why the procedure mentioned above doesn't work is because the  
/etc/powerdown program performs a `getuid()` system call to check which user  
is running the program. This call returns the real user ID of the user and  
not the effective user ID obtained with the `set uid` bit.

The only way to execute the power-down without actually logging on is to  
make an entry in the file /etc/passwd in which the starting program is  
/etc/powerdown, and the user ID is "0" (zero). This entry could look like:

```
stop::0:1000:Entry to powerdown the system:/:/etc/powerdown
```

We do not recommend powering down the system this way, because there are  
several processes running in the background when the system is in an init  
level other than "s" (single-user mode).

The proper way to power is to execute the shutdown command, and, when the  
machine reaches "Single User Mode", execute the /etc/powerdown command.

A/UX: LaserWriter IINTX Connection Documentation Error

=====

Article Created: 7 September 1989

### Article Change History

-----

08/31/92 - REVIEWED

- For technical accuracy.

### TOPIC -----

In the A/UX Local System Administration (030-5595-B) manual (page 7-34, step 2), the user is instructed to attach the LaserWriter IINTX to the A/UX host via a SCSI cable in addition to the serial connection. Is this correct? There was no mention of the reason for this connection, nor was there mention in the LaserWriter manual. I have the most recent version of the A/UX documentation.

If this is incorrect, what is the potential damage to systems connected this way?

### DISCUSSION -----

The instructions mentioned above are wrong. There is no need to connect the SCSI cable between the LaserWriter IINTX and the A/UX host.

Also, there is no potential damage having the systems connected that way.

AppleFax Modem: How It Handles Busy Signals During Transmission

=====

This article last reviewed: 7 September 1989

TOPIC -----

When several "envelopes" are "stuffed" and prepared for later transmission, and the AppleFax Modem dials the addressed number on the envelope and encounters a busy signal:

- Will the AppleFax continue to dial until it gets through?
- Will it cycle through all of the envelopes and come back to the ones it could not send on the first pass?
- Will they not be sent until the send time tomorrow?

DISCUSSION -----

If the AppleFax modem is unable to connect with another Fax machine, the envelope is not sent, and an error occurs requiring you to Restore the envelope before it can be sent again. The AppleFax will, however, continue to transmit all other envelopes to other accessible faxes.

Once the AppleFax has attempted to send an envelope, the envelope's icon is dimmed, and you are unable to open or change the envelope. When checking the activity report after sending an envelope, if you discover that errors occurred and that you need to resend the envelope, you must first restore the envelope to its original condition:

1. Select the dimmed envelopes that you want to restore.
2. Choose Restore Selected Envelopes from the AppleFax menu.

The envelopes are no longer dimmed and can be opened, changed, and re-sent as necessary.

## AppleWorks: Early Versions Don't Support RAM Cards

Revised: 9/22/89  
Security: Everyone

AppleWorks: Early Versions Don't Support RAM Cards

=====

This article last reviewed: 7 September 1989

TOPIC -----

I have upgraded my Apple IIe by installing a 512K memory expansion card.

When I tried to run AppleWorks 1.0.1, the memory accessed was only 10K. And when I tried AppleWorks 1.1.1, I got a message saying "not enough memory, need 128K". All this after installing the card and ProDOS. A diagnostics test, however, confirms that the 512K of RAM is available: yet AppleWorks still won't run.

DISCUSSION -----

Early versions of AppleWorks do not support memory cards; you need version 1.3 or later. Version 2.1 is available from CLARIS at an upgrade price. Contact them for an upgrade order form.

For more information, search on "CLARIS" in the Tech Info library.

## A/UX: VT220, Intermedia, and Cartridge Drives (12/95)

Revised: 12/1/95  
Security: Everyone

A/UX: VT220, Intermedia, and Cartridge Drives (12/95)

=====

Article Created: 7 September 1989  
Article Reviewed/Updated: 1 December 1995

TOPIC -----

### 1. VT220 on the Console

I've ported an accounting system to A/UX (which can be used with Apple's national character set). I'm using VT220 terminals to generate masks for this application. Neither the console nor "term" give full VT220 functionality. Is there a way to run VT220 on the console? Will "term" support VT220 in the near future, or has someone already added this feature to "term"? Is there anyone else interested in getting VT220 either as console or in "term"?

### 2. Intermedia and Printing

A/UX is set up as an Intermedia Server and Client with a SuperMac CommCard for printing over LocalTalk. Printing over LocalTalk works fine from a shell and from a Macintosh application. I can choose a LaserWriter in the Chooser when running Intermedia but printing fails. No job goes to the queue and the printer dialog box shows the default setting for "LaserWriter" and "3.1" for the Laser Prep version!

### 3. Infinity and A/UX

I'm using Infinity removable cartridge drives (40 turbo) extensively. I've tried to use them as exchangeable user filesystems under A/UX without success. "mkfs" didn't work, nor did the setup utility. When I finally tried dp, I got error messages:

```
- dp /dev/dsk/c4d0s31  
- c4d0s31: error: more data than SCSI device requested
```

then four times:

```
generic disk c4d0s31
retry limit: logical block 0, physical block 0
/dev/rdisk/c4d0s31: no such device or address
warning: size of disk indeterminable
warning: this will hinder validity checking on input
warning: unable to read disk partition map
```

Is there a way to use these disks with A/UX?

#### DISCUSSION -----

1. The current A/UX 3.0 keyboard/console driver emulates a VT102 terminal. The A/UX Toolbox "term" terminal emulator program also emulates a VT100. None can fully provide full VT220 functionality at this time.

Your concern on the console and the Toolbox "term" with VT220 terminal emulation capability will be submitted to A/UX Engineering as an enhancement request.

2. We have tested the newly installed IRIS Intermedia package and had the same printing problem you described. According to the "IRIS System Administrator's Guide (page 39), "The printer should be set up as a 9600-baud serial printer, and it must be connected to the Intermedia server." If this is true, then there is a problem printing to an AppleTalk printer via the SuperMac CommCard.

3. No one here seems to have had any success using the removable cartridge disk drive from either Mass Microsystems or Infinity. According to Mass Microsystems, it seems that their driver works with Mac OS but not with A/UX. If anyone has successfully used a removable cartridge drive under A/UX, please Link  
TECH.COMM.

## A/UX: pagesize Information (9/94)

Revised: 9/21/94  
Security: Everyone

A/UX: "pagesize" Information (9/94)

Article Created: 7 September 1989  
Article Reviewed/Updated: 21 September 1994

TOPIC -----

I assume that a click in A/UX is the normal SysV 2K (2048 bytes). In /usr/include/sys/mmu.h, if the NEW\_PMMU is defined, the PAGESIZE is defined as (1 << PAGESHIFT), and the PAGESHIFT is earlier defined as PS4K, that is, 11. So the logical shift makes it 2048. I am unsure if the A/UX kernel has NEW\_PMMU set or not.

I need the click size information for shared memory tuning.

DISCUSSION -----

From our research, the A/UX 1.1 kernel is compiled with the NEW\_PMMU defined in the kernel MAKEFILE.

In the /usr/include/sys/mmu.h file:

|                             |                                 |
|-----------------------------|---------------------------------|
| The PAGESIZE is defined as  | #define PAGESIZE (1<<PAGESHIFT) |
| The PAGESHIFT is defined as | #define PAGESHIFT PS4K          |
| The PS4K is defined as      | #define PS4K 12                 |

From the above formula, the PAGESIZE can be calculated as 1 << 12, which equals 4096. It's 4K, not 2K.

The command, called "pagesize", can also be used to display the current system page size.

## A/UX: IPC Tools (9/94)

Revised: 9/21/94  
Security: Everyone

A/UX: IPC Tools (9/94)

=====  
Article Created: 22 September 1989  
Article Reviewed: 21 September 1994

TOPIC -----

If I remember correctly, Sys V.2 had two really good tools by which you could check the use of shared memory, segment sizes, flags on semaphores, and so on. I think this tool was called `icps`.

The other tool could be used for releasing shared memory segments. I did not find any equivalent tools under A/UX. I think this tool was called `icpr`. Please correct me if these tools exist under A/UX.

Otherwise, I would ask for an RFC because to tweak shared memory you need to know how much is in use at the moment. The problems with shared memory segments is that they hang in the system after the program has used them.

DISCUSSION -----

The two IPC tools, which you mentioned above, are called "`ipcs`" and "`ipcrm`", and both DO exist in A/UX 3.0.

The "`ipcs`" allows you to print the status of the active interprocess communication facilities.

The "`ipcrm`" allows you to remove one or more specified interprocess communication facilities, such as message, semaphore, or shared memory identifiers.

For more details, type "`man ipcs`" and "`man ipcrm`" in the A/UX Command Shell.

A/UX: Determining Available Memory (9/94)

=====

Article Created: 7 September 1989  
Article Reviewed/Updated: 13 September 1994

TOPIC -----

After I start up A/UX, and the splash screen is gone, how can I determine how much memory is installed in the system and how much is available? I am looking for a shell command, if it exists.

DISCUSSION -----

There is no command shipped with A/UX that will provide this information. It would be possible to write a program that returned these values, but none are included.

We don't think these values change frequently enough to require much attention. Users generally know when they change the amount of installed RAM, and the available memory only changes when the kernel is reconfigured.

A/UX 2.0: Select About the Finder in the Apple menu (while in the Finder)

A/UX 3.0: Open the Memory Control Panel for a display of both physical and virtual memory. ( Control panels can be found under the Apple menu)

## LocalTalk PC Card: Problem Using with Zenith Systems

Revised: 9/22/89  
Security: Everyone

LocalTalk PC Card: Problem Using with Zenith Systems

=====

This article last reviewed: 7 September 1989

TOPIC -----

I am using two LocalTalk adapters, one in a Zenith 8088 machine, and the other in a Zenith 386 machine.

Each time I try using them, the system locks. I have version 1.0 of the software, which came with the adapter. An article in the Tech Info Library states that, most likely, there is an IRQ conflict, or that the system needs to be told that the IRQ has been changed. I double checked for IRQ conflicts (I even removed all of the adapters in the machine that may have caused the conflict), and I have the proper command in my autoexec, as described in the manual.

Do you know of anything else to try, or do you know of some incompatibility with Zenith machines?

DISCUSSION -----

Although you have removed all of the add-in cards in the Zenith machines, there is still a possibility of an IRQ or DMA conflict.

Most Zenith PCs come with built-in serial and parallel ports. On some models, the serial ports use the same interrupt as the default interrupt for the LocalTalk PC Card. You should check the Zenith documentation for information on the interrupt lines used by the built-in ports.

Since you are using the original software that came with the card, we assume you are using LW.EXE. We recommend that you obtain the current release of AppleShare PC.

## Ethernet-to-Cable TV/Broadband Network Connectivity

Revised: 9/22/89  
Security: Everyone

Ethernet-to-Cable TV/Broadband Network Connectivity

=====

This article last reviewed: 7 September 1989

TOPIC -----

I'm interested in creating Ethernet drops onto the broadband, such as cable TV. Do you know specific companies who make this hardware product, or is it normal Ethernet drops that customers would use?

DISCUSSION -----

Ethernet over broadband cable is definitely not a standard coax Ethernet drop. The cable types are different, and only a portion of the bandwidth of the broadband cable is used for Ethernet while the rest remains free for video and audio information.

There are a number of companies that provide the hardware for implementing Ethernet over broadband cable. They include Digital Equipment Corporation, Bridge Communications, and Allen-Bradley Company. We want to emphasize that configuring this type of network is not plug-and-play, and you need to work closely with a network consultant or one of the above companies to determine the best configuration for your needs.

For more information, search on the above company names in the Tech Info library.

## AppleTalk: Cable TV/Broadband Network Connectivity

Revised: 12/12/90  
Security: Everyone

AppleTalk: Cable TV/Broadband Network Connectivity

=====

This article last reviewed: 15 November 1990

TOPIC -----

Can AppleTalk operate over cable TV wires? If so, how?

Since cable TV mainly uses coax-type cable, how do I make the connection? If it needs to be done serially (connection to the cable), would a Hayes InterBridge-type product be able to do this?

For home use, the only thing I can think of is using Liaison (if asynchronous is still the way to go) in the Macintosh.

Can any of the solutions work with Apple II computers? This is needed for home use to connect to a ANS network to a school.

DISCUSSION -----

It is possible to have Ethernet channels running on a broadband network, which is typically used in cable TV installations. It is important that the group responsible for the cable be intimately involved in this process since this is not a plug-and-play situation. There are a number of different alternatives possible once you have the hardware and software support for Ethernet in place on the cable network.

Usually, you would connect routers, such as the AppleTalk Internet Router, to the Ethernet drops from the broadband, and all of the other Macintoshes are connected to the Internet via routers. The routers then would be the only Macintoshes required to have Ethernet boards. You also could use FastPaths, GatorBoxes, or Macintoshes running Liaison as the routers.

Network Resources also offers several products that allow Macintosh users to connect to broadband. Their MultiGate 2000 hardware router connects LocalTalk to broadband, as if connecting a LocalTalk network to Ethernet via a router. Their MultiGate Bridge connects any combination of broadband, Ethernet, and

fiber optics. These solutions do not require running Ethernet on broadband. For more information on their products, search on "Network Resources and broadband" in the Technical Info Library.

A Hayes InterBridge would not be a solution because it is a LocalTalk-to-LocalTalk bridge, and you need an Ethernet connection.

For the asynchronous connection, Liaison definitely seems a good choice since it also has the other capabilities mentioned above.

On the Apple II front, we are not aware of anything that will provide remote, serial AppleTalk access similar to what is available for the Macintosh.

We strongly suggest that you get assistance from a network consultant capable of assisting you in all phases of this type of setup. You should also be aware that anyone doing this will need full approval from whomever owns and operates the cable system.

## Kodak DataShow: Pixels Limits Prevent Showing of Full Screen

Revised: 9/22/89  
Security: Everyone

Kodak DataShow: Pixels Limits Prevent Showing of Full Screen

=====

This article last reviewed: 7 September 1989

TOPIC -----

When using the Kodak DataShow for giving presentations, the problem is that the overhead projection system places these buttons below the viewing area on the screen display as well as on the projected display. In other words, I don't have access to the buttons to start an animation or set the volume, for example. This happens whenever I have the projection system connected to the Macintosh. If the projection system is not connected to the Macintosh, the screen displays the entire screen including the buttons at the bottom.

DISCUSSION -----

The Kodak DataShow displays only 512x342 pixels regardless of which computer you're using. Since this becomes your screen size for your presentation, anything outside of these boundaries will not be accessible. You could try one of the screen extender packages, such as Stepping Out. Otherwise, you need to work with a projection system that is capable of displaying more pixels.

## LaserWriter IINTX: LaserJet Emulation and Landscape Problem

Revised: 9/22/89  
Security: Everyone

LaserWriter IINTX: LaserJet Emulation and Landscape Problem

=====

This article last reviewed: 7 September 1989

TOPIC -----

I am printing in Landscape rather than Portrait mode to a LaserWriter IINTX in LaserJet emulation mode.

I am using a PC-clone and driving the printer from dBASE III+. All the HP command codes I send to our printer work except the code for Landscape mode. When I send this, nothing happens.

The code being used is:

```
CHR(27)+"&10"
```

I have tried using a zero instead of letter O and also put a CHR(13) at the end of the command, and it still does not work.

DISCUSSION -----

It appears that you should be using a different escape sequence. According to our documentation, you should try the following:

in decimal:  
`chr(27)+chr(38)+chr(108)+chr(49)+chr(79)`

in ASCII:  
`esc "&l10"`

Substituting the 49 with a 48 should put you back in Portrait mode.

## MacAPPC: Using it to Create an IBM Compatible File Server

Revised: 7/27/93  
Security: Everyone

MacAPPC: Using it to Create an IBM Compatible File Server

Article Created: 22 September 1989  
Article Reviewed/Updated: 23 July 1993

MacAPPC does not inherently provide AFP-compatible file services for the Macintosh. MacAPPC is a development tool kit that allows the user to write custom transaction programs to provide a variety of functions to the end user using the LU6.2 verb set.

To Apple's knowledge, there is no AFP-compatible file service available for any IBM mainframe operating system. Someone could write one, using MacAPPC, but they would have to implement AFP on the mainframe end and create a custom application for the Macintosh. The Macintosh side would have to be written to "tunnel" or encapsulate AFP frames within SNA. One would have to examine their environment a bit closer to get a handle on what mainframe components would be required to accomplish this.

However, using APPC as a basis, a "simple" file server on the mainframe could be created which would allow the devices on the remote network to connect to it. This, however, would not be an AFP-compatible file server.

Something to investigate is a package called XCOM 6.2 from Legent Corp. (formerly Spectrum Concepts). XCOM, currently in development, sits on top of MacAPPC and permits file transfers to an IBM mainframe with a HyperCard front end. This package will support binary formats, allowing you to distribute Macintosh files from the mainframe, as well as text. Spectrum Concepts likes to position this as an RJE replacement package. This package, however, will not give you AFP/AppleShare look, feel, or functionality.

If there are 3X74 remote controllers installed, a 3270 file transfer package, like Avatar's, can provide a similar service in the 3270 world. A 3X74 replacement with similar capability is the Netway 1000. These packages allow MacBinary transfers, in addition to regular binary and text. These also do not have an AFP/AppleShare look and feel. DCA's MacIrma and Simware could also be used, but they provide binary and text transfers only, not MacBinary.

By using these packages in conjunction with a TSO-partitioned data set, one

could create a "simple" file server, but without the ease of operation of AppleShare. Transport, in this instance, is file transfer. By transferring the files as text, one could share files with IBM PCs.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

## AppleFax Modem: Serial NB Card Doesn't Support Multiple Modems

Revised: 9/22/89  
Security: Everyone

AppleFax Modem: Serial NB Card Doesn't Support Multiple Modems

=====

This article last reviewed: 7 September 1989

TOPIC -----

I who would like to use six AppleFax Modems on a single Macintosh with a Serial NB Card.

1. Is this possible (that is, are there drivers available for this card)?
2. Is there any software that supports this situation?

DISCUSSION -----

We are not aware of any drivers that support the Serial NB Card for the AppleFax modem. Also, since the modem is treated as an output or Chooser-style device, only one can be supported for output purposes. In terms of receiving input, the software also works with only one modem. We do not know of any third-party software that supports multiple modems.

## VT100 Emulation Package that Can Adjust Screen Display Size

Revised: 7/24/92  
Security: Everyone

VT100 Emulation Package that Can Adjust Screen Display Size

=====  
Article Created: 22 September 1989  
Article Last Reviewed: 8 September 1989  
Article Last Updated: 17 July 1992

TOPIC -----

Is there a product that you can recommend that will use the full 13-inch Apple screen to do a VT100 emulation?

I am using Macintosh IIcx systems to trap data from a Hewlett Packard via a VT100 emulation session. The emulation packages I am using cannot take advantage of the whole of the screen in VT100 mode.

Before I started using Macintosh, the dumb terminals had a screen size of about 11 to 12 inches square. Unfortunately, the Macintosh emulation packages, such as OPAL (VIA Systems, Inc. is the U.S. distributor), MicroPhone II, and VersaTerm PRO, leave a 1-inch strip at the bottom and right of the screen when doing the emulation, and the actual size of the display is smaller than before.

Certainly, the screen can be resized to fill the 13-inch screen, but at 12-point, the 80 characters leave this 1-inch strip. In 14-point, the 80 characters flow off of the screen by about 3 to 4 characters.

I need more control over the actual font being used--either a 13-point font, or a slightly different font might solve the problem.

DISCUSSION -----

A possible solution would be to use Red Ryder from FreeSoft. This package has the ability to choose the font size you want as long as the font you choose is installed in the application. The application has a specific font with ID 98 that it looks for when setting the font size. You could build a 13-point font from one of the existing sizes that would then be accessible from Red Ryder. Building this font requires using a Font Editor, such as Fontastic from Altsys Corp.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

## 3M DC 2000 Tape Cartridge: Estimated Shelf Life

Revised: 4/11/91  
Security: Everyone

3M DC 2000 Tape Cartridge: Estimated Shelf Life

=====

This article last reviewed: 8 September 1989

TOPIC -----

What is the shelf life of a DC 2000 tape?

DISCUSSION -----

According to 3M Data Storage Products Division, the expected shelf life of a DC 2000 mini-data cartridge is 2 to 5 years. This shelf life is based on the active life of the lubricants used in the cartridge. The shelf life is affected by environmental conditions (temperature, humidity, and so on). The magnetic tape itself is rated for use, not shelf life, normally at 5000 passes.

For more information, search on "3M" in the Tech Info library and contact their Data Storage Products Division.

## MFLOPS Ratings: How They're Calculated and Used

Revised: 3/19/93  
Security: Everyone

MFLOPS Ratings: How They're Calculated and Used

=====

Article Created: 22 September 1989

### Article Change History

-----

03/16/93 - RETITLED

- From "Motorola 68020/68030: How To Calculate MFLOPS Ratings"

### TOPIC -----

Does Apple publish MFLOPS ratings for the various Macintosh computers? How accurate is this rating for comparing system performance between vendors?

### DISCUSSION -----

MFLOPS (Million Floating Point Operations Per Second) is a measurement generally used in reference to supercomputers rather than personal computers or workstations. Measuring MFLOPS is an inaccurate art, at best. The reference manuals we consulted all stated that an MFLOPS rating can be misleading. The issue that causes MFLOPS ratings to be suspect is that not all instructions take the same time. On the 68881, a single instruction can take from 29 to over 600 machine cycles.

From Motorola's 68020/68030 Performance Report:

"Benchmarking microprocessors is much like water-witching. Everyone wants to use the results but are skeptical of the 900-methods. From the user's point of view, the best benchmark to use in making a decision on a given microprocessor is to run the code which will be run in the final application. This, however, is usually difficult at best, and expensive and time consuming at least. Since running the actual code is usually not feasible, most users and all microprocessor manufacturers turn to either synthetic benchmarks - ones that simulate real-world conditions - or small standard benchmark programs which are designed to

indicate real-world performance. Not everyone can agree on what simulates real conditions; thus, there are numerous benchmark programs available, each written to test some aspect of performance that the writer is interested in testing."

For many of the same reasons that Apple does not publish MIPS ratings and those stated above, Apple does not publish MFLOPS ratings. However, you can calculate this value on your own.

Using chapter 6 of the Motorola MC68881 Floating-Point Coprocessor User's Manual, figure the average time for a floating-point operation. Here's that problem mentioned above. Do you add the times for all instructions and divide by the number of instructions? Do you pick a few "popular" instructions and average their times? Do you pick the instruction that requires the least amount of time (very sneaky)?

We suggest the first method. For the sake of this discussion, let's say that value is xx cycles/instruction.

Assume that the floating-point unit and the microprocessor are clocked one for one. On the Macintosh IIX, this value would be 15.6672 m-cycles/sec.

Invert the first number and multiply by the second giving you m-instructions/sec (MFLOPS).

$$\begin{array}{ccccccc} 1 \text{ instructions} & 15.6672 \text{ million cycles} & & 15.6672 & \text{million instructions} \\ \text{--} & \text{-----} & * & \text{-----} & = & \text{-----} & \text{-----} \\ \text{xx} & \text{cycle} & & \text{sec} & & \text{xx} & \text{sec} \end{array}$$

It is generally assumed that the 68882 is 1.5x faster than the 68881.

## MicroExplorer: Compatible with NuBus

Revised: 9/22/89  
Security: Everyone

MicroExplorer: Compatible with NuBus

=====

This article last reviewed: 8 September 1989

TOPIC -----

Does the Texas Instruments MicroExplorer work in the Macintosh IIX and the Macintosh IICX?

DISCUSSION -----

The Texas Instruments MicroExplorer is NuBus-compatible. It will work with the Macintosh II, the Macintosh IIX and the Macintosh IICX.

The MicroExplorer card comes with 4MB of memory but is usually configured with an additional 4MB of memory. This extra memory comes on an expansion board that takes the space of a second slot although it does not use a connector. In the Macintosh II and the Macintosh IIX, two slots are used. Because there are only three slots in the Macintosh IICX, Texas Instruments bends a pin so that the MicroExplorer only uses one slot. You can then use two additional cards in the Macintosh IICX.

Unless you want only 4MB of memory, the Macintosh IICX configuration must be purchased from Texas Instruments as a system because they bend the pin. The Macintosh II and the Macintosh IIX configuration can be bought as a package, or the card can be bought separately.

For more information, search on "Texas Instruments" in the Tech Info library.

## Omnis: Lack of Virtual Memory Limits Large Database Sorting

Revised: 9/22/89  
Security: Everyone

Omnis: Lack of Virtual Memory Limits Large Database Sorting

=====

This article last reviewed: 8 September 1989

TOPIC -----

A have a huge (1.5-million record) Omnis database that they need to sort using a Macintosh II with 8MB of RAM.

The system is running under Finder, and the system has been stripped of all INITs, extra fonts, even the RAM cache is off. I am able to sort up to 1.2 million records, but shortly thereafter, Omnis returns an error message that the system is out of memory.

Part of the problem lies with Apple's operating system, and the fact that it only addresses 8MB of RAM. The other part of the problem is with Blyth, and the fact that they do the complete sort in RAM.

It has been suggested that I add some of the new 4MB SIMM strips that are available for the Macintosh II, but this will cost upwards of \$5,000 to \$10,000 just to test, and might not even work.

What should I do?

DISCUSSION -----

We contacted Blyth Software, and they confirmed that their sort routines bring all of the information they need into RAM. Their sort routines do not write anything out to disk to allow for larger amounts of information to be sorted.

Omnis has a line at the bottom of the sort window that tells you how many records it can sort. This number is calculated according to how much memory you have available at the time. This information can, at least, can help you to determine if the sort will be complete or not before you run the sort.

We are not aware of any workaround for this problem. Adding 4MB SIMMs will

not work. The Macintosh OS only addresses a maximum of 8MB of memory. It is possible that with System Software 7.0 and virtual memory, there will be enough addressable memory for this sort to work, but that obviously is not a solution now.

This is not a hardware limitation, but rather a software limitation. It is possible to write software that will write information to disk as it is sorting, so that such a large amount of RAM is not needed. FoxBase+/Mac, for example, writes information to a temporary file when it is sorting. It requires that you have twice as much disk space available as the information that you want to sort. A possible solution would be to change databases; however, we realize that with a custom database already written and all of the data in it that this is not a trivial thing to do.

## GS/OS 5.0: Can Create Accented and Special Characters

Revised: 9/22/89  
Security: Everyone

GS/OS 5.0: Can Create Accented and Special Characters

=====

This article last reviewed: 8 September 1989

TOPIC -----

I want to be able to display accented French characters on a localized Apple IIGS. What are my options?

DISCUSSION -----

The announcement of GS/OS 5.0 has some information that pertains to this very subject:

"The ability to create accented and special characters directly from the keyboard, something particularly important to customers working with legal and math symbols and other languages, is also a great addition."

GS/OS 5.0 has the capability of generating accented characters in the same manner as is done on the Macintosh.

## LaserWriter IINTX: Space Amounts for an Attached Hard Drive

Revised: 9/22/89  
Security: Everyone

LaserWriter IINTX: Space Amounts for an Attached Hard Drive

=====

This article last reviewed: 8 September 1989

TOPIC -----

This is a request for basic information about hard drives that are attached to the LaserWriter IINTX. Specifically, I would like additional information on the following issues.

- 1) How can a person determine how much space is available on the drive? Let's say I have 60 fonts downloaded to the drive and would like to check available space to determine how many additional fonts I can download. The "diskstatus" operator tells how many Kbytes are available, but what about the ratio of cache versus font storage? Is it with the "userdiskpercent" operator?
- 2) At what point does the system/printer alert me that the space available on the drive will limit performance? Does it depend on the ratio of font caching space versus font storage space, or an actual total MB value of space that's available?
- 3) What affect does the amount of free space have on the performance of the LaserWriter speed?

DISCUSSION -----

The following information was obtained from the LaserWriter Reference Manual from Addison-Wesley (ISBN 0-201-19258-6), Chapter 2 "Working With Fonts", and the LaserWriter IINT/NTX Manual from Apple (030-3215-A), Appendix A "LaserWriter II Upgrades".

- 1) Initialization of a hard disk attached to a LaserWriter IINTX allocates 20% of the disk space to font storage and 80% to font caching. The LaserWriter Font Utility informs the user how much space is available for additional font storage. The "diskstatus" operator returns the number of pages currently available and the maximum number of pages

available (a page being 1024 characters). The operator "userdiskpercent" returns the percentage of disk space allocated for user files. The operator "setuserdiskpercent" allows setting the percentage of space on the drive allotted for user files. This operator also removes the least recently used cached bitmaps from the disk file system until there is enough free space.

- 2) The Font Utility application issues the warning to the user when the storage percentage is high enough to threaten font caching performance. Since the LaserWriter IINTX automatically increases the storage percentage as needed, this warning is probably related to the number of fonts on the disk versus the amount of cache space left on the disk.
- 3) As long as there is enough font cache space to create the needed bitmaps for the downloaded fonts on the hard disk, there should be no decrease in throughput of the LaserWriter as available space on the hard disk gets smaller. The warning from the Font Utility should be adequate.

## Apple IIGS: Hard Drive Always Starts Up From 1st Partition

Revised: 9/22/89  
Security: Everyone

Apple IIGS: Hard Drive Always Starts Up From 1st Partition

=====

This article last reviewed: 8 September 1989

TOPIC -----

I'm using a 20MB hard drive with an Apple IIGS. I used the Advanced Disk Utilities to partition the drive into four partitions. I installed AppleWorks on the first partition and the System files on the fourth partition. Every time I start up the system, it launches AppleWorks first, which is not what I want.

Is there some way to control which partition gets opened first?

DISCUSSION -----

There is no method available for specifying which partition the system will start up from.

As the software is currently written, the system always starts up from the first partition. If you want to start up with the System files first, it is necessary to have the Finder, and so on, in the first partition. Then have your other applications follow in partitions of ascending numerical order.

There are currently no plans to change this method of operation.

MacLink Plus: Explanation of Errors 106 and 124

=====

This article last reviewed: 8 September 1989

TOPIC -----

I've had a report of errors 106 and 124 appearing in MacLink Plus when going from Macintosh to Macintosh via the cable provided. What do these mean?

DISCUSSION -----

These errors are generated by, and are specific to MacLink Plus. We called DataViz Technical Support and received the following information:

Error 106 is a "can't connect error" and occurs when MacLink Plus cannot complete a connection.

Error 124 is a "port set error". This error indicates that there is a port conflict. An example of this is having both MacLink Plus and AppleTalk set to the same port.

For more information, we suggest contacting DataViz Technical Support at 203-268-0030.

## Apple EtherTalk Card: Revisions J and K Explained

Revised: 10/4/89  
Security: Everyone

Apple EtherTalk Card: Revisions "J" and "K" Explained

=====

This article last reviewed: 8 September 1989

TOPIC -----

What is the latest revision of the Apple EtherTalk adapter? Is there a specific revision required to support the Internet Router and AppleTalk Phase 2?

DISCUSSION -----

The latest revision of the Apple EtherTalk Card is Revision "K".

To be assured of good performance when there is a lot of network traffic, you should use Apple's EtherTalk Card with EtherTalk 2.0. You should use Revision "J" of the EtherTalk Card. Revision "J" fixed a problem in earlier revisions that caused data corruption.

When a Macintosh IICx is used as an EtherTalk 2.0 workstation, then Revision "K" of the EtherTalk Card should be used. Revision "K" fixed a problem that caused a Macintosh IICx with only one card installed not to start.

Both problems occur only in rare instances, but to be safe, Revision "J" or "K" should be used.

## Inter•Poll: Asynchronous and Lookup Interval Options Explained

Revised: 3/1/93  
Security: Everyone

Inter•Poll: Asynchronous and Lookup Interval Options Explained

=====

This article last reviewed: 8 September 1989

TOPIC -----

In the Inter•Poll "Settings" command of the "Special" menu, there are two options called "Asynchronous Interval" and "Lookup Interval". The documentation says that "Lookup Interval" determines the wait time between asynchronous lookups (page 74), and it's the same thing for "Asynchronous Interval". What is the difference?

DISCUSSION -----

On page 74 of the "Inter•Poll Network Administrator's Guide", there is a screen shot of the "Setting" dialog. The "Lookup Interval" describes, in seconds, how often NBP Lookup packets are sent to the AppleTalk network.

The "Asynchronous Interval" and "Asynchronous Count" come into play when the lookup packet or packets do not generate a response. The "Asynchronous Count" field describes how many times a resend occurs, and the "Asynchronous Interval" field describes how long (in 8-tick increments) the system waits between resends.

## Internet Router: Correction to Administrator's Guide

Revised: 2/6/90  
Security: Everyone

Internet Router: Correction to Administrator's Guide

=====

This article last reviewed: 8 SSeptember 1989

TOPIC -----

On page 129, of the AppleTalk Internet Router Administrator's Guide, (Appendix A: Planning an AppleTalk Internet, Figure A-8) it appears that the cable segments are LocalTalk (printer is on the same cable segment) and the workstations are all LocalTalk.

How do you get workstations and printers physically connected to the router via LocalTalk to be in separate zones as the picture describes?

How do you build a work group consisting of a few LocalTalk users, LocalTalk printers, and some EtherTalk users in one zone?

The only workstation zone selectable under the Apple-Control Panel-Network is for EtherTalk and TokenTalk? Is this correct? Is the zone for the LocalTalk printers always the single LocalTalk zone name?

DISCUSSION -----

The diagram on page 129 of the "AppleTalk Internet Router Administrator's Guide" is misleading. A LocalTalk network can be associated with only one zone. This is the same as it was with AppleTalk Phase 1.

With AppleTalk Phase 2, any node on an AppleTalk network (other than LocalTalk) can belong to any zone selected from a list of available zone names. This would include EtherTalk 2.0 and TokenTalk 2.0. More information on this is on page 4 of the "AppleTalk Phase 2 Introduction and Upgrade Guide".

## LaserWriter: Workaround to The Namer Utility Naming Problem

Revised: 4/9/93  
Security: Everyone

LaserWriter: Workaround to The Namer Utility Naming Problem

=====

Article Created: 8 September 1989

### Article Revision History

-----

04/09/93 - REVISED

- To include information on the LaserWriter Utility

### TOPIC -----

I'm having problems naming a LaserWriter Plus using The Namer 2.1 utility.

I'm trying to name the printer "2040/1825 EUC LW+", but The Namer creates a name of "2040/1825 EUC LW+ ". Notice the space AFTER the + character.

What is in this name that causes this to happen? I am sure that I did not type the space when using the Namer.

### DISCUSSION -----

The Namer utility, including version 7.0, appears to add a trailing space to some printer names. We have been unable to determine what causes the space to be added.

Here is an alternate method for renaming the printer:

The printer name is stored as a string in the persistent parameters of all LaserWriters. This string can be changed by the following PostScript program:

```
serverdict begin 0 exitserver
statusdict begin (NEWNAME) setprintername
```

In your case, replace "NEWNAME" with "2040/1825 EUC LW+". This program can download to the LaserWriter in batch or interactive mode. Note that the brackets are required. Make sure you have selected the correct LaserWriter using the Chooser before downloading this program (so you don't rename the

wrong LaserWriter). The name can be up to 31 characters and should consist entirely of printing characters--the "@" and ":" cannot be used.

This problem has been cured in version 7.4 of the LaserWriter Utility.

## Macintosh: How To Configure When Using Different Monitors

Revised: 7/8/92  
Security: Everyone

Macintosh: How To Configure When Using Different Monitors

=====

Article Created: 8 September 1989  
Article Last Reviewed: 7 July 1992  
Article Last Updated:

TOPIC -----

I carry my Macintosh IICx back and forth from my home to the office. At home, I have a monochrome monitor; at the office, a Portrait Display. The Macintosh IICx contains interface cards for both monitors, and I want to be able to easily set the menu bar for each monitor.

When using the Macintosh IICx with the Portrait Display, I can still "see" two monitors represented when I open the Monitors CDEV. I can drag the menu bar to the smaller monitor so it will start up on that screen when I'm at home.

However, at home with the monochrome monitor, I cannot set the menu bar to appear on the Portrait Display. The Monitors CDEV 3.3.1 and 4.0 won't let me select the Portrait Display unless it is plugged into the card. So when I get to the office and start up, there is no menu bar. I have to power down, remove the regular video card, and power up again.

As a fix, it has been suggested that I keep a copy of the Monitors CDEV after setting it up for the Portrait Display. At home, I can drag the current CDEV out of the System Folder, and put the "office version" in the System Folder, so it will start up properly without my having to remove the normal video card. This is inconvenient, and I would prefer that the CDEV allow me to specify the Portrait Display when the card is present.

Is there some new version of the Monitors CDEV that fixes this problem? It appears that the possibility of different monitors in multiple locations was overlooked when the CDEV was written. I imagine there are many customers in similar situations.

DISCUSSION -----

The fix recommended above will not work. The "Monitors" CDEV does not save any settings within itself. They are stored in the System file in a resource called the "scrn" resource with an ID = 0. Replacing the "Monitors" CDEV does not affect the settings in any way. The Portrait Display Video Card is an intelligent card that senses at startup if a display is attached. If no display is attached, the video card does not make itself known to the system and does not show up in the "Monitors" CDEV.

We have, however, a solution that should work. With the Portrait Display attached, open the Monitors CDEV and move the menu bar to the icon that represents the Portrait Display and don't adjust the screen that the menu bar is on. When you take the computer home and plug in the monochrome monitor, the menu bar will show up on the monochrome monitor. This happens because the system thinks that only one video card is installed and displays all information to the monochrome monitor. When you take the computer to work and plug in the Portrait Display, the menu bar will appear up on the Portrait Display because of the values stored in the "scrn" resource in the System file.

There is nothing that can be done to the "Monitors" CDEV to resolve this issue.

Article Created: 8 September 1989  
Article Reviewed/Updated: 26 September 1994

TOPIC -----

Does Apple distribute a disk that tells developers how to modify an 8-bit Apple Macintosh Video Card to produce conventional NTSC color video as an unsupported feature? How do I get it?

DISCUSSION -----

The information is actually a CDEV/INIT with a documentation file.

The CDEV/INIT file is called "Macintosh II Video Utility"; the documentation file is called "Video Utility Read Me."

## 3COM EtherLink: Running AppleTalk and EtherTalk Concurrently

Revised: 4/12/91  
Security: Everyone

3COM EtherLink: Running AppleTalk and EtherTalk Concurrently

=====

This article last reviewed: 23 August 1989

TOPIC -----

Regarding the concurrent use of AppleTalk and EtherTalk:

I have 3COM's EtherLink/NB interface cards using EtherTalk and running 3COM's 3+Share for the Macintosh. Here is my procedure:

- 1) I log on to the Internet Server using the Chooser. (The CDEV is set to EtherTalk.)
- 2) I link the appropriate Servers, printers, shared folders, etc.
- 3) I change the CDEV back to LocalTalk, and a warning dialog box appears telling us that we will lose our current connection. Choose OK.
- 4) I go back to the Chooser and select a LaserWriter from the AppleTalk network.
- 5) I still have an EtherTalk connection! I haven't lost anything, and AppleTalk is active.

I have always thought that a workstation could use only one AppleTalk connection at a time (although it may be physically connected to several networks, sending and receiving data over the selected network connection).

Why and how does this 3COM EtherLink continue to work? Doesn't the LAP Manager send packets to the connection selected in the Control Panel?

DISCUSSION -----

As a user, you can have access to only one physical network at a time through the link access you specify via the Control Panel.

During tests, when we change our network device in the Control Panel, we do lose our connections to our network services. We suspect that the 3COM software is not actually using AppleTalk, but instead is implementing its own protocol stack, which bypasses even the LAP specified by the Network Control Panel device.

If this is the case, then only the AppleTalk-based services would be lost while all of the 3COM services would remain unaffected including the servers. This would mean that you actually don't have EtherTalk, but you do have the 3COM Ethernet connection still up and running.

## HyperCard 1.2.1: Insufficient Memory when Printing

Revised: 9/22/89  
Security: Everyone

HyperCard 1.2.1: Insufficient Memory when Printing

=====

This article last reviewed: 23 August 1989

TOPIC -----

HyperCard chokes after I print around 140-150 of the 284 cards in a certain stack. I'm using HyperCard 1.2.1 on a Macintosh II with 2MB of memory running MultiFinder.

DISCUSSION -----

This is probably an out-of-memory error, so try printing without MultiFinder running. Here are some other options you should try (in order):

- 1) Compacting the stack immediately before printing.
- 2) Using HyperCard 1.2.2.
- 3) Write a script that sets the lockmessages and lockrecent properties to true, then go to each card of the stack and issue a Print Card menu command. This is the least-recommended solution, due to the time and trouble involved.

TOPIC -----

Sometimes my wireless telephone will ring when I do something on my Macintosh IIcx. Is it possible for the IIcx to set off my phone?

DISCUSSION -----

Under certain conditions, EMI or RFI levels from the Macintosh IIcx could be high enough to set off the ringer of a wireless telephone sitting on its cradle (the condition does not exist when off the cradle).

A Macintosh IIcx with HD40 SC and 2MB RAM with Apple 8-bit video card and AppleColor monitor running Director performed this trick. Every time an error condition existed, the telephone was triggered when we closed the error dialog box.

We did not try other software. MoC certification number of the telephone is 5382227A (Send Freq = 49.770 MHz, Recd Freq = 46.710 MHz). The telephone was approximately 4 feet from the monitor, and it is currently Bell's top-of-the-line model (Promenade 1250).

Complete testing has not been done, but garage door or alarm systems may also be affected.

## Macintosh II: How It Handles Color Versus CGA, VGA, and EGA

Revised: 7/8/92  
Security: Everyone

Macintosh II: How It Handles Color Versus CGA, VGA, and EGA

Article Created: 23 August 1989  
Article Last Reviewed: 7 July 1992  
Article Last Updated:

TOPIC -----

This article discusses how the Macintosh handles color in comparison to CGA (Color Graphics Array), VGA (Video Graphics Array), EGA (Enhanced Graphics Array) and other color standards.

DISCUSSION -----

Background

-----  
CGA

The first color standard for the MS-DOS PC-style computers was CGA (Color Graphics Adapter or Color Graphics Array). The CGA standard can display two colors from a palette of 16 colors at its maximum resolution of 640 by 200. The output of this card is a TTL digital RGB signal.

PGC

The next standard for color on MS-DOS computers was the IBM PGC (Professional Graphics Card), which has a 640 by 480 resolution with 256 colors from a palette of 4096. The PGC provides an analog output. This card gained very little acceptance because EGA, the next standard, provided better price/performance.

EGA

EGA (Enhanced Graphics Array) provided some backward compatibility with the CGA standard. The first EGA had a maximum resolution of 640 by 350 with 16 colors from a palette of 64. The current EGA standard (EGA enhanced) is 640 by 480 with 16 colors. Both EGA standards use a TTL digital RGB output.

VGA

When the PS/2 computers were introduced, the VGA standard came into existence. There are three color graphics modes on the VGA (Video Graphics Array) card: 640 by 480 with two colors, 640 by 480 with 16 colors, and 320 by 200 with 256 colors. The 16- and 256-color modes have a palette of 262,144 colors. The lower resolution of the 256 colors has limited its use with commercial software. With the VGA standard, an analog RGB output is used.

#### MS-DOS Color

-----  
With the CGA, EGA, EGA enhanced, and VGA, it is possible that each card may require a different driver to be installed for each of the individual applications that is run on each computer. It is possible, for example, for a company with five MS-DOS computers to have five different drivers for the same program: on System One a CGA card from Manufacturer A, on System Two an EGA card from Manufacturer B, on System Three an EGA enhanced card from Manufacturer C, on System Four an EGA enhanced card from Manufacturer D, and on System Five a VGA card from Manufacturer E. Each of these systems is running Lotus 1-2-3. For each system to display the 1-2-3 graphs, each system may need a driver for each individual card. Each of these systems will most likely be displaying in different resolutions and with a different number of colors.

Even within one graphics card standard, when moving from one card manufacturer to another, different drivers may be required for the same program. Also, within one graphics card standard, some third parties may have decided to change the rules; that is, 640 by 480 by 16 colors is the standard in EGA enhanced, but there is a card that uses 800 by 560 by 16 colors.

These resolutions remain constant whether a 9-inch or a 19-inch screen is used--creating a situation where an application cannot depend on the screen display to represent any type of "what you see is what you get" environment. A graphic object that is 2 inches by 2 inches on one screen may become 4 inches by 4 inches on another screen.

With the wide variety of possible color display devices for the MS-DOS world, consistency is very difficult to maintain.

#### Macintosh Color

-----  
On the Macintosh, there is more consistency, even when moving from black and white graphics to full 32-bit color graphics. Card developers and software developers need not be concerned about which application or which video card they are going to work with. Both the hardware companies and the software companies focus their resources on QuickDraw. A driver for a particular application is not necessary in the Macintosh environment. Users needn't be concerned about installing drivers to use a particular application.

The typical Macintosh screen is 72 pixels per inch. There is a difference from one screen product to the next--but only a small difference. This allows for a consistent display. A 2-inch by 2-inch

image remains very, very close to 2 inches by 2 inches from screen to screen.

If you have a smaller screen, you have fewer pixels; however, the pixels are very, very close to the size of any other Macintosh screen. This constant pixel size has been a tremendous benefit for the publishing market because an image on Macintosh "A" is very close to the same image on Macintosh "B"-- unlike the MS-DOS world. Since all Macintosh video cards use the same reference (QuickDraw) for image work, it doesn't matter who manufactured the video card: the image appears the same.

With 32-Bit QuickDraw now available, the Macintosh can also display photo-quality images--not available in the CGA, EGA, and VGA environments.

When the graphics environment is enhanced, applications do not need to undergo major changes to continue to work in the new and enhanced graphics model. For example, programs that ran in Macintosh 1-bit display configuration continue to run in the 32-bit display configuration. These applications may not take advantage of the new environment, but they generally continue to work without modification.

CGA and EGA cards require a digital RGB display monitor. VGA and Macintosh can, in many instances, use the same multisync monitors.

## Macintosh-to-Wang: Emulation VS Serial Communication

Revised: 9/22/89  
Security: Everyone

Macintosh-to-Wang: Emulation VS Serial Communication

=====

This article last reviewed: 23 August 1989

TOPIC -----

How can I connect and transfer files between a Wang VS 5000 and a Macintosh II over a modem?

DISCUSSION -----

There are several ways to connect the Macintosh computer within the Wang environment. The most common implementations rely on basic Wang terminal emulation and terminal emulation with file transfer and document conversion capabilities. Below is a complete solution, including Wang terminal emulation and asynchronous file transfer.

Basic Wang Terminal Emulation  
-----

Any Macintosh application that supports VT100 emulation -- such as inTalk or MacTerminal software -- can emulate a standard VT100 terminal on a network using the Wang VS. This allows the Macintosh computer to function as a Wang workstation by direct or modem connection to the Wang-provided asynchronous device controller (ADC) or enhanced asynchronous device controller (EADC). These controllers let remote terminals execute Wang software applications, with the following limitations:

- The standard Wang keyboard includes 32 function keys, a Help key, and a Cancel key, all of which are heavily used in Wang applications. With the Macintosh computer and VT100 emulation software, the user needs to memorize several keystrokes to signify each of these keys.
- With the described MacTerminal connection, it is not possible to transfer files between the Macintosh computer and the Wang VS.

Terminal Emulation with File Transfer and Document Interchange

-----

The DataViz MacLink Plus/Wang VS software provides a bridge between Wang word processing and Macintosh applications, including word processing and desktop publishing applications. It also provides two-way file transfer and document translation using the standard Macintosh user interface, while allowing the Macintosh user to access Wang Office electronic-mail services.

Macintosh documents can be converted to standard Wang word processing documents and stored on the Wang VS in a one-step process. Wang VS documents can be sent to the Macintosh computer and automatically translated to MacWrite, Microsoft Word, or WordPerfect format, allowing documents created on the Wang VS to benefit from Macintosh desktop publishing capabilities.

Data files can be transferred in both directions and then translated into a variety of formats. Wang data files can be converted and used on the Macintosh computer as Microsoft Excel spreadsheets. Macintosh files can be stored on the Wang VS in MacBinary format for use by other Macintosh users, and also can be stored in binary format for use by MS-DOS personal computer users -- in all, more than 45 translators are provided.

You can also read mail received via Wang Office electronic mail and copy received files and documents to the Macintosh computer. You can create and send Wang Office memos and packages containing memos, documents, and data files (even MacBinary and binary files) to Wang users, as well as other Macintosh computer and IBM PC users.

A special version of MacLink Plus/Wang VS is available for Macintosh connectivity via the Wang VS TC, TCP, or MLTC ports. The full range of file translators is available for file transfer and conversion. (Wang does not support terminal emulation capability through these ports.)

#### Document Conversion with Smart Kid

-----

Smart Kid from Interpreter, Inc. is a hardware and software product that allows documentation conversion between Wang VS or Wang OIS and various word processors and personal computers. Many systems and software packages are supported, including Microsoft Word and WordPerfect on the Macintosh computer, WP and WP Plus on the Wang, WordPerfect and Massll on Digital's VAX, and a number of IBM PC word processors and dedicated word processors. Smart Kid permits almost 100-percent file conversion, including headers, footers, and footnotes and translates directly from Wang WP and WP Plus into Macintosh word processing formats.

#### Terminal Emulation for Document Transfer and Conversion

-----

VSterm from MacSoft and VsCom/Macintosh from M/H Group (the leading vendor for IBM PC-Wang VS connectivity software) provide Wang 2110 terminal emulation for document transfer and conversion. With VSterm, any PC with a serial port can

emulate the Wang 2100 or VT100 terminals, exchange documents and data with the Wang VS, and convert Wang VS data to popular PC formats. VsCom/Macintosh provides Wang VS 2100 terminal emulation, including quick screen response, complete support of Wang WP graphics and characters, and flexible access to Wang function keys. The program also provides file transfer and conversion between Macintosh and Wang word processing formats.

MacSoft also offers a program called Converse that provides file transfer and conversion through the Wang VS TC-IOP ports, providing a relatively simple, inexpensive solution for file transfer and conversion.

#### MacBLAST for Asynchronous Communication

-----

MacBLAST communications software interfaces with BLAST for the Wang VS/OS (Revision 6.4 or later, equipped with TCP/IP boards and asynchronous ports with ADC/EADC options). MacBLAST provides high-speed, error-free file transfer and text file format-conversion for integrating the Macintosh computer with Wang computer systems. MacBLAST transfers binary data, text, or graphics.

MacBLAST and Wang VS BLAST can be used to create file transfer links or dial-up networks between Wang VS computers and any number of remote Macintosh computers or PCs. MacBLAST uses standard phone lines or X.25 networks to provide reliable, high-speed communications unaffected by line noise or propagation delay on satellite-routed calls and X.25 packet networks.

MacBLAST features include on-line help, automatic dialing, and scripting for creating unattended operations, custom menus, and seamless integration within Macintosh applications.

## Viruses Rarely Spread Between Different Machine Types

Revised: 9/22/89  
Security: Everyone

Viruses Rarely Spread Between Different Machine Types

=====

This article last reviewed: 29 August 1989

TOPIC -----

Can an infected Macintosh on a network spread a virus to an IBM host?

DISCUSSION -----

A virus rarely spreads between different machine types. (A rare occurrence of this was the virus that infected thousands of UNIX systems through a hole in the mail system. This was possible since the virus actually recompiled itself on each of these machines. Even so, it would not have been possible across operating systems.)

Thus, there should be no way for a virus on a Macintosh to spread to an IBM host. The host would need to be executing 680x0-based code and using all of the basic mechanisms of the Macintosh operating system.

It IS possible, if the host is being used as a file server, for files to become infected. These files still would affect only Macintoshes connected to the host, not the host itself.

## AppleShare PC: Resetting Timeout

Revised: 9/22/89  
Security: Everyone

AppleShare PC: Resetting Timeout

=====

This article last reviewed: 29 August 1989

TOPIC -----

I have several PCs coexisting with Macintoshes on a PhoneNET network. They are printing to LaserWriters -- primarily the LaserWriter IINTX, but also a LaserWriter IINT.

The Macintoshes are running Microsoft Word on the DOS end, and are having problems printing because Microsoft Word does not release the document when it reaches the end: I have to wait for the timeout.

I can use the DA pop-up application to change the timeout from 3 minutes to a few seconds, but this is a lot of trouble. Can this be automated?

DISCUSSION -----

You can use the command line interface to the DA; the command is called "ANET" and is documented in the AppleShare PC 2.0 manual (Apple part #030-3002-A). The specific subcommand you want is CONNECT, which has an option for setting the LaserWriter timeout value. You also can obtain the exact format of the command by entering the following command at the DOS prompt:

```
ANET HELP CONNECT
```

Once you have the specific command you desire, enter that line in the AUTOEXEC.BAT file so that it is executed at startup, automatically connecting you to the LaserWriter of your choice with your desired timeout values.

## HyperCard: How to Send a Macro Keystroke Sequence

Revised: 9/29/90  
Security: Everyone

HyperCard: How to Send a Macro Keystroke Sequence

=====

This article last reviewed: 17 August 1990

TOPIC -----

Is there a way to create a button in HyperCard to send a macro keystroke sequence (such as AutoMac or QuicKeys)?

DISCUSSION -----

HyperCard's "type" command does not generate a keydown event, which is needed for this sort of macro. It might be possible to write an XCMD. An easier way is Dewi Williams' excellent "PostEvent" stack. Not only does it call Tempo II and QuicKeys macros, it's invaluable for posting carriage returns to dialogs (that is, the Print Report dialog) without user intervention. It's available in the ordinary places: CI\$, GENie, MacNet, user groups, and so on.

## Macintosh: Storage at Extreme Temperatures and Altitudes

Revised: 6/8/92  
Security: Everyone

Macintosh: Storage at Extreme Temperatures and Altitudes

=====

Article Created: 22 September 1989  
Article Last Reviewed: 1 June 1992  
Article Last Updated:

TOPIC -----

Can the Macintosh withstand non-operating temperatures of -80 deg C? Can the Macintosh and a hard drive be modified to operate at altitudes of 12,000 feet?

I am interested in using a Macintosh at the South Pole. The elevation is 10,000 feet, but atmospheric conditions add the equivalent of approximately 2000 feet, for a total altitude factor of 12,000 feet.

The equipment will be installed during the summer (temp is -30 deg C to -40 deg C), which is within Apple's storage temperature specification guidelines. If there were a generator problem during the winter, the temperature could drop to -80 deg C for a period of time.

DISCUSSION -----

There is a great probability of damage to any Macintosh used in the environment you describe.

Apple's storage temperature guidelines are specified for storage only. Under no circumstances should the system be operated at anything under 0 deg C. In fact, if the Macintosh is stored at its minimum temperature, it would need to be returned to above 0 deg C for AT LEAST 2 hours before operation.

Also, the battery on the logic boards of all Macintosh II computers is not good for any temperature under -40 deg C. Lubricants in a hard drive would also solidify at those low temperatures.

We know of no way to modify the Macintosh to work in such conditions.

## NTSC Video: How To Avoid Flicker on Macintosh

Revised: 7/16/90  
Security: Everyone

NTSC Video: How To Avoid Flicker on Macintosh

=====

This article last reviewed: 29 August 1989

TOPIC -----

This article discusses how to overcome Macintosh video "flickering" in an NTSC environment. (NTSC is the current broadcast standard for television signals.)

DISCUSSION -----

Macintosh video in an NTSC environment is commonly beset by flickering images.

The flicker is most noticeable when 1-pixel horizontal lines are used in the display. Due to the technique used for NTSC displays, 1-pixel lines are actually on the screen only half of the time. NTSC video is displayed at 30 frames per second, with each frame having 2 fields, or 60 fields per second. A field consists of alternating lines of the frame: odd lines are displayed in the first field, even lines in the second field.

Most video images contain material that exists in each field (each half of the frame). This allows these portions of the image to remain on screen at all times, persisting through both fields. A 1-pixel line exists on the screen only in alternating fields -- half of the time.

This is the nature of NTSC and is not specific to the Macintosh -- ANY computer graphics only 1 pixel wide have a tendency to flicker. There are various methods for resolving this annoyance.

Several companies have converters that capture both fields and display them at the same time. A similar technique is beginning to appear in consumer television receivers, generally labeled "extended definition TV", or EDTV: with both fields displayed, the 1-pixel lines are always on the screen. Information on such professional-level devices can be found in ads in computer graphics magazines.

Mass Microsystems ColorSpace F/X NuBus card for the Macintosh II family uses a

similar approach to provide stable 1-pixel lines on an NTSC video device.

Another approach, used by many computer graphic artists, is to simply use 2-pixel lines for any subject being sent to the NTSC environment.

In some situations, like trainings and demos, the only noticeable flicker is in a Macintosh window's title bar. The software approach for avoiding the annoying title bar flicker is to use an INIT called "NeVR". This INIT makes the title bar a solid pattern rather than the normal 1-pixel horizontal lines.

NeVR is available on many of the public access networks and bulletin boards.

AppleShare PC 2.0: Compatible Network Cards

=====

This article last reviewed: 29 August 1989

TOPIC -----

This article lists cards known to be supported by AppleShare PC 2.0

DISCUSSION -----

AppleShare PC 2.0 supports the following cards:

3COM EtherLink II  
3COM EtherLink MC (MicroChannel)  
IBM Token Ring 802.2 (long card)  
IBM Token Ring 802.2 (short card)  
IBM Token Ring Adapter/A (MicroChannel)  
DayStar Digital MCA LocalTalk Card (MicroChannel)  
Apple LocalTalk PC Card

Only the cards listed above have drivers included with AppleShare PC 2.0.

Other third-party network cards may also be able to support AppleShare 2.0.

For more information, contact the card manufacturers directly.

## Apple HD-20 (Non-SCSI): Which Macintosh Computers Support It

Revised: 3/4/91  
Security: Everyone

Apple HD-20 (Non-SCSI): Which Macintosh Computers Support It

=====

This article last reviewed: 27 February 1991

TOPIC -----

With what Macintosh models can I use a serial HD-20?

DISCUSSION -----

Support of the serial HD-20s is not tied to System Software, but to the ROM in the respective systems.

The following Macintosh models have support for the serial (non-SCSI) HD-20 built into ROM:

- Macintosh 512Ke
- Macintosh Plus
- Macintosh SE
- Macintosh Classic
- Macintosh IIfx
- Macintosh Portable

The following Macintosh models do NOT have this support built in:

- Macintosh SE/30
- Macintosh II
- Macintosh IIX
- Macintosh IICx
- Macintosh IISI
- Macintosh IIfx
- Macintosh LC

For more information on the serial HD-20, see the article "Old HD20 and New Mac SE/30".

## HyperCard: suspend and resume Messages

Revised: 9/22/89  
Security: Everyone

HyperCard: "suspend" and "resume" Messages

=====

This article last reviewed: 29 August 1989

TOPIC -----

Why doesn't HyperCard generate the "suspend" and "resume" messages when running under MultiFinder? Is there a workaround?

DISCUSSION -----

HyperCard uses the "sublaunch" mechanism of the "\_Launch" trap when the "open" command is issued to run other applications. The "sublaunch" mechanism behaves one way with MultiFinder off, another with MultiFinder on.

With MultiFinder turned off, the sublaunch mechanism causes HyperCard to issue a "suspend" message and then quits. The application specified in the "open" command is then launched. When this application is exited, HyperCard is relaunched. HyperCard is able to determine that it is being relaunched and issues the "resume" message.

With MultiFinder turned on, the sublaunch mechanism acts as if the user double-clicked on an application, causing the application to launch. HyperCard never has to quit, so a "suspend" or "resume" message is never generated.

There is currently no way to work around this situation.

## HyperCard: resume Handler Under MultiFinder

Revised: 6/24/90  
Security: Everyone

HyperCard: "resume" Handler Under MultiFinder

=====

This article last reviewed: 29 August 1989

TOPIC -----

My HyperTalk programming manual says "resume" is sent up the chain of handlers when you quit an application launched from HyperCard. I put the following handler into the "Stack Script":

```
on resume
    put "Hello World"
end resume
```

When I quit the application, nothing happens. Do you have any suggestions?

DISCUSSION -----

HyperCard does not generate "suspend" and "resume" messages when running under MultiFinder. This is probably why the stack script resume handler is never called.

If MultiFinder is not being used, another resume handler is probably called first, and is not passing the message to the next object in the hierarchy.

Messages are passed through the object hierarchy in the following order:

- Buttons and fields
- Cards
- Backgrounds
- Stacks
- Home Stack
- HyperCard

Based on this hierarchy, we would check for resume handlers in the following scripts: the card script for the card from where the application was opened, and the background script for the card from where the application was opened.

(NOTE: The "suspend" and "resume" messages are not passed to buttons and fields.)

If a resume handler is found, add the line "pass resume" just before the "end resume" line in the handler. For example:

```
on resume
  -- Whatever script that happens to be here
  -- Whatever script that happens to be here
  -- Whatever script that happens to be here
  -- Whatever script that happens to be here
  pass resume
end resume
```

## Macintosh: 1-Bit Video Incompatible With Adobe Illustrator

Revised: 9/22/89  
Security: Everyone

Macintosh: 1-Bit Video Incompatible With Adobe Illustrator

=====

This article last reviewed: 29 August 1989

TOPIC -----

My Adobe Illustrator 88 1.6 bombs on a Macintosh IICx with the Macintosh 1-bit Video Card installed. Have you heard of any problems with the 1-Bit Video Card and software compatibility?

DISCUSSION -----

Versions of Adobe Illustrator 88 prior to version 1.7 are not compatible with Macintosh 1-Bit Video Card.

Adobe Illustrator 88 version 1.8.3 is the latest version, and it does work properly with the Macintosh IICx and the Macintosh 1-Bit Video Card.

## Routing Table Maintenance Protocol (RTMP): AppleTalk Phase 2

Revised: 9/22/89  
Security: Everyone

Routing Table Maintenance Protocol (RTMP): AppleTalk Phase 2

=====

This article last reviewed: 29 August 1989

TOPIC -----

Here are some questions and answers about changes to RTMP (Routing Table Maintenance Protocol).

DISCUSSION -----

Q) Are Routing Table Maintenance Protocol (RTMP) timers still at 10-second intervals?

A) Yes, the RTMP packets are still sent out every 10 seconds.

Q) Are RTMP validity timers still at 20-second intervals?

A) The validity timer is still based on 20 seconds.

Q) Do routing tables propagate only when changes are perceived, or are the Phase 1 algorithms still being used?

A) The algorithms used are different, but the changes do not affect when the tables are propagated. The changes specifically affect the amount of data sent in each packet. AppleTalk Phase 2 routers only pass information about routers that are located on the other side of the router. For example:

A----B----C----D

Router B passes information about routers C and D to router A, but it does not tell router A about itself.

## LaserWriter: Connecting to IBM PC and PS/2 Computers

Revised: 3/4/90  
Security: Everyone

LaserWriter: Connecting to IBM PC and PS/2 Computers

=====

This article last reviewed: 29 August 1989

TOPIC -----

This article discusses how to connect LaserWriter printers to IBM PC and PS/2 computers.

DISCUSSION -----

To connect IBM PC-XT and all PS/2 systems (all have DB-25 Male Serial connectors from the CPU) to the LaserWriter families, use a Serial Null Modem cable. Here is the cabling scheme for Apple cables:

```
[CPU -- PC or PS/2 DB-25 (Male)] to
[(Female) DB-25 Female-to-Female Gender Changer (Female)] to
  [(Male) 590-0037 (Straight through DB-25 Serial cable) (Male)] to
    [(Female) 590-0166 (Modem Eliminator Cable) (Male)] to
      [(Female) LaserWriter Serial Port]
```

To adapt the IBM PC/AT or other 80286 class MS-DOS machines to the DB-9 serial port, add a DB-9-to-DB-25 adapter between the CPU and the Female-to-Female DB-25 adapter. Radio Shack stocks both adapters. The DB-9-to-DB-25 is Radio Shack part number 26-1388 or 26-265. The DB-25 Female-to-Female is Radio Shack part number 26-1495. If the Apple 590-0166 is not readily available, use a Radio Shack Null modem (Modem Eliminator) adapter.

Testing the Connection

-----

This test, if successful, prints the current DOS directory on the LaserWriter. Before doing the steps below, make sure that a) Everything is connected correctly; and b) the IBM-PC serial port to be used is configured as a known COM: port (like COM1: or COM2:).

Note: The test assumes that COM1: is the serial port. If you're using a different COM port, substitute it as appropriate in step 2 below.

Follow these steps:

1) Set the printer to Diablo emulation mode.

- On a LaserWriter or LaserWriter Plus, set the rotary switch to SPECIAL.
- On a LaserWriter IINT, set switch 1 to ON and 2 to OFF.
- On the LaserWriter IINTX, set switch 1, 2, and 3 to ON and 4, 5, and 6 to OFF.

2) Power on the LaserWriter and the MS-DOS machine. At the DOS prompt, type the following:

```
MODE COM1:96,n,8,1
```

```
MODE LPT1: = COM1:
```

```
DIR > LPT1:
```

```
ECHO ^D > LPT1:
```

Note: The "^D" stands for the keystroke sequence Control-D. This is the "end-of-transmission" command. Note: Use ^D instead of ^L to avoid problems with the printer expecting more information and maintaining the connection after a print.

If all went well, you should have a printout of the current DOS directory. If nothing happened, check these three things:

- Make sure that you have access to the MODE command.
- Make sure that the serial port you think is "there" really is "there".
- Make sure that all cabling is snugly connected.

If you got a good printout, then the physical and logical integrity of the connection between the MS-DOS computer and the LaserWriter is good. Once you have successful test results, you can switch modes on the LaserWriter and expect it to perform well in the MS-DOS-to-LaserWriter printing environment.

However, if you are printing a long document and pieces of the document appear to be missing from the output, the problem is probably not in the fundamental connection between the printer and the computer. This symptom will most likely appear in a PostScript production environment.

The problem probably has to do with the "Handshake" mode settings in the printer and the computer. ("Handshaking" is the process where the computer expects the printer to tell the computer to pause briefly while it finishes the current print job.) The "XON/XOFF" handshaking protocol is supported by both series of printers (LaserWriter and LaserWriter II). The "DSR/DTR" protocol is only supported by the LaserWriter IINT/NTX family.

Further questions about MS-DOS and LaserWriter connectivity are answered in Appendix C of the "LaserWriter IINTX Owner's Guide".

## Macintosh: Startup Problems When Using CD-ROM (5/96)

Revised: 5/23/96  
Security: Everyone

Macintosh: Startup Problems When Using CD-ROM (5/96)

=====

Article Created: 22 September 1989  
Article Reviewed/Updated: 23 May 1996

TOPIC -----

When I start my Macintosh with the CD player attached and turned on, everything works fine. But when I have a CD-ROM disc inserted in the player before I start it, the Macintosh will not boot, and freezes.

DISCUSSION -----

In a majority of cases, the system doesn't crash when a CD-ROM is in the drive as described above. However, some non-startup CD-ROM discs have been mastered with data in the boot blocks. When this happens, the computer starts to boot up from the CD-ROM disk but is unable to find a valid system folder and will, then freeze or crash. If a CD is mastered with the first two blocks left blank, the system won't attempt to use the disc as a boot device.

The problem is that the default block size for a CD-ROM drive is 2048 bytes, whereas the default block size for a hard drive is 512 bytes. This difference can cause the system to read unanticipated areas which may lead to the problem described above.

## MacWorkStation: Protocol-Based Communications Problem

Revised: 9/22/89  
Security: Everyone

MacWorkStation: Protocol-Based Communications Problem

=====

This article last reviewed: 12 April 1989

A developer of a TCP/IP network reports the following problem. Uploads of window or file contents are causing serious problems resulting in line drops. This occurs during EZ read Text (T008), Read Text (T009), Select Existing File (F017), and probably during EZ Read File Fork (F007) and Read File Fork (F008).

The developer is currently using the Simple ASCII transport layer (ID = 2) with 7 data bits. Unfortunately, data in the ranges <00>-<1F> and <80>-<FF> may be contained within windows or files. In particular, if there is a carriage return <0D> within the data, then the IBM mainframe front-end processor (FEP) takes this as an end-of-line character, sends the packet to CP, which sends the packet to the application, which processes it.

Meanwhile, MacWorkStation continues to send the remainder of the packet up until the final carriage return, which it uses to signal end-of-line. Unfortunately, the characters following the first carriage return cause CP interrupts, leaving the virtual machine in CP mode. After some number of interrupts, CP determines that the line is too noisy to continue and signals the FEP to drop it.

The problem here is that they are using a protocol in an unsupported fashion. The serial protocol driver (ID=2) that uses start and stop characters is not designed to support the transfer of binary data, or any data that might contain nonstandard characters. The best choice would be to use the serial driver (ID=1) that supports binary data and should be able to handle the transfer of carriage returns. If this is unacceptable, request a copy of the source for serial driver version 2.

## LaserWriter IINTX: How to Network PS/2 and Macintosh Computers

Revised: 3/4/90  
Security: Everyone

LaserWriter IINTX: How to Network PS/2 and Macintosh Computers

=====

This article last reviewed: 24 August 1989

You can connect multiple IBM PS/2 computers, Macintosh computers, and Apple LaserWriters, so that the connected computers are networked with each other and the LaserWriters. This enables Macintosh and IBM computers to share data and printers through the network interfaces. The following solutions describe the specific interfaces and their configurations.

### DayStar Digital Solution (Direct LocalTalk Connection)

-----

This solution uses a LocalTalk MicroChannel card within IBM PS/2 MicroChannel systems. The MicroChannel systems are networked using the LT200MC MicroChannel LocalTalk card for MicroChannel bus PS/2s by DayStar Digital. The card uses AppleTalk network protocols and associated software so that MicroChannel PS/2s can communicate with other AppleTalk system components, like the LaserWriter IINT and IINTX. The card comes with software for PS/2s to connect to AppleTalk printers. AppleTalk network products like TOPS are reported to work with the card, too. AppleShare PC 1.0, 1.1 and 1.2 is reported to be incompatible with the DayStar card. For more details, search the Tech Info Library under "DayStar".

### 3COM Solution (Ethernet to Server to Serial Connection)

-----

Another solution is to use the EtherLink MC PS/2 card from 3COM. This is a more complex solution, because it comprises several components. The card connects MicroChannel PS/2s to Ethernet. The PS/2s can print to a 3COM 3S200 print server serially-connected to a LaserWriter II. Macintoshes may connect through an Ethernet interface card too or directly through the LocalTalk port of the 3S200 server. 3COM servers do not support AppleTalk connections to LaserWriters and can only connect serially. The 3S200 server supports file, mail services, and print services.

Routers (Ethernet to router to LocalTalk connection)

-----  
A Kinetics FastPath, Gator Box, or an Apple Internet Router can route EtherTalk data from Ethernet connected AppleTalk systems like Macintoshes, PCs, MicroChannel PS/2s, and DEC VMS systems. The computer systems must have an Ethernet, Tokenring, or LocalTalk interface installed with an AppleTalk driver and appropriate network software. Some PC software packages that run with this configuration are TOPs and AppleShare PC 2.0\*. By using the routers, the EtherTalk systems can print to LocalTalk LaserWriters directly through the routers or through print servers from companies like 3COM, Pacer, Alisa, or Apple.

\* A MicroChannel PS/2 EtherNet or TokenRing Card using AppleShare PC 2.0 must use an AppleTalk Phase 2 router. The Apple Internet Router is a phase 2 router.

PS/2 Notes

-----  
There are six PS/2 models 25, 30, 50, 60, 70, and 80. Each model can also be bought in a different configuration. The low-end models 25 and 30 retain a PC and/or AT bus architecture that works with the Apple LocalTalk PC card.

## AppleWorks 2.0: Problems Printing to Networked ImageWriter

Revised: 9/22/89  
Security: Everyone

AppleWorks 2.0: Problems Printing to Networked ImageWriter

=====

This article last reviewed: 29 August 1989

TOPIC-----

I have an AppleShare network, including Apple IIe, Apple IIGS, and Macintosh systems, with AppleWorks 2.0 running from the server. I cannot print to the LocalTalk ImageWriter II using AppleWorks, but can print to it from a Macintosh.

DISCUSSION-----

The difficulty in printing concerns the version of AppleWorks being run from the server. The ability to print from Applesoft indicates that the hardware is properly configured. AppleWorks 2.0 is not licensed for, nor designed for, running from an AppleShare server. For a version of AppleWorks licensed and designed for running from a server, use AppleWorks version 2.1N. Be sure, in AppleShare Admin under the Apple II menu, to set the user's account to the desired printer. The alternative would be to run AppleWorks 2.0 from a local disk.

## AppleWorks: Problems Printing to LocalTalk ImageWriter

Revised: 9/22/89  
Security: Everyone

AppleWorks: Problems Printing to LocalTalk ImageWriter

=====

This article last reviewed: 29 August 1989

TOPIC-----

AppleShare was recently installed at a client school. I am having problems printing from AppleWorks on the Apple IIe's to a LocalTalk Imagewriter. Here is some background:

- There are no problems accessing the file server.
- The LocalTalk ImageWriter was set as the default printer for Apple II users.
- The AppleShare Print Spooler is NOT on the file server.
- LocalTalk Cards were placed in Slot 7 of the IIe's.
- I added a printer in AppleWorks configured to print to Slot 7.
- If I run CHOOSER.II the printer shows up. If I reselect the printer I still have the same problems.

When I print from AppleWorks I get NOTHING. If I go to BASIC I can type PR#7 and talk to the printer. How can I print to the LocalTalk'd ImageWriter from AppleWorks?

DISCUSSION-----

We cannot get the results you describe. With the Workstation card in slot 7, a networked ImageWriter, a slot 7 ImageWriter selected in AppleWorks, and AppleWorks 2.0 running, we can print across the network with no difficulties.

Our configurations have included all combinations of:

- AppleWorks version 2.0, with an ImageWriter assigned to slot 7

- ProDOS 8 versions 1.4 and 1.6
- Apple IIe, enhanced, with the Workstation card in slot 7
- ImageWriter II with AppleTalk option
- Chooser II version 1.2
- AppleShare II Workstation versions 1.0 and 1.1

In all cases the document printed without need for special actions.

Our boot disk contained

- ProDOS
- ATINIT
- Selector.System
- Sys.Apps (a sub-directory containing:)
  - Basic.System
  - Logoff
  - Logon
- Chooser (a sub-directory containing:)
  - Chooser.II
  - Chooser5.OVR
  - IWEM
  - Chooser4.OVR
  - Chooser3.OVR
  - MTXABS.0
  - Chooser2.OVR
  - Chooser1.OVR
  - Chooser.0
- Namer (a sub-directory containing:)
  - Namer.II
  - Namer.0
  - MTXABS.0
- Access ( a sub-directory containing:)
  - Access
  - Priv.0
  - MTXABS.0
  - Priv1.OVR
  - Priv2.OVR
  - Priv3.OVR
  - Priv4.OVR
- AWORKS (a sub-directory containing:)
  - Aplworks.System
  - SEG.00
  - WWSS
  - SEG.M0
  - SEG.EL
  - SEG.XM
  - SEG.RM
  - SEG.M1

- SEG.PR

Our procedure followed these steps:

- 1) Boot with the above configured disk.
- 2) The selector window will be displayed; select and run Chooser II.
- 3) Press the Down cursor key to highlight "AppleTalk ImageWriter II".
- 4) Press Return to select. The name of the networked ImageWriter should appear in the to right scroll box. If the name does not appear:
  - a) Press the Tab key three times. You are now in the scroll box allowing you to chose between LocalTalk and Serial. Highlight LocalTalk and press Return.
  - b) Press Tab twice. You are now in the top left window. Highlight 'AppleTalk ImageWriter II'. Press Return. The name of the networked ImageWriter should now appear.
- 5) Press Tab twice. Use the Down cursor key to highlight the name of the networked ImageWriter. Press Return to select.
- 6) Press Open-Apple-Q to exit Chooser II.
- 7) Run AppleWorks.
- 8) Select Other Activities, Printer Information.
- 9) Verify a printer is designated as an ImageWriter in Slot 7. If no ImageWriter is set for slot 7, then do these three steps:
  - a) Delete a printer if all three printers are currently defined
  - b) Add a printer. Use ImageWriter. Set for Slot 7.
  - c) Give a name that indicates it is a network printer,i.e., "Network IW II".
- 10) Return to your document. Press Open-Apple-P to access the printer routines.
- 11) Answer the "Print from?" question. (In our test, we answered from beginning)
- 12) Answer "Where...to print the file?" question with the network printer.
- 13) Answer "How many copies?" question.
- 14) On pressing Return after answering the last question, AppleWorks will send the document over the network to the ImageWriter. There was a slight delay between the screen refresh and the printing.

If you have any further questions about this sequence of events please Link TECH.COMM with details of what is taking place.

## Super Serial Card: Using with Machine Language (12/96)

Revised: 12/16/96  
Security: Everyone

Super Serial Card: Using with Machine Language (12/96)

=====

Article Created: 22 September 89  
Article Reviewed/Updated: 16 December 1996

TOPIC -----

This article describes assembly language addressing methods for the 6502 and 6551 microprocessors through the Super Serial Card.

DISCUSSION -----

The 6502 does a false read to the current page. This is inherent in the 6502 design. A false read occurs during a read to memory. The 6502 will hold the target address + 1 line open after it accesses the target address. This does not alter the contents of the address but can affect a memory-mapped I/O device that is toggled by the address line.

The false read does not affect the Super Serial Card as none of the card's functions are set when the address line is held open by the false read. However, for good programming to an I/O device, where false reads could toggle a function, you should use the indirect indexed-addressing mode with the address for your indirect accesses in the zero page.

The following example is available in the Tech Info Library and uses the absolute, indirect-addressing method; it has been modified here as an example of indirect, indexed-addressing. The program uses zero-page addresses \$FA and \$FB, because these are generally unused by both DOS and BASIC. See pages 74 and 75 of the "Apple II Reference Manual" for a map of the zero-page locations.

Super Serial Card: Accessing It Through Machine Language

-----

Although Apple's Super Serial Card can be used from Applesoft BASIC, it is often desirable to use machine language to increase the speed with which characters are sent and received. The assembler program below illustrates a method of communicating with another computer through the Super Serial Card. You may use this routine as a starting point for your own program.

On page 291 of the "Apple IIe Reference Manual" and on pages 261 to 265 of the Apple IIc Reference Manual, there are lists of the registers and entry points used by routines resident in the Super Serial Card. The equates in the program below use these locations, as well as input/output hooks found in the Apple II family of computers.

The initialization routine (INIT) stores the address of the Super Serial Card's initialization routine in CSW (the Apple II monitor character output hook). This activates the card for output by jumping to COUT. Following this, DOS or ProDOS hooks are reinstalled.

The OUTput routine checks the 6551 status port bit 4. If this is equal to zero, the previous character has not yet been sent, so we must check the status byte again until that register is clear. When the value in bit 4 becomes one, the 6551 is ready to send another character. To do this, store the data in the transmit register (TDREG) of the chip.

Bit 3 of the status port is checked by the INput routine. If this bit is zero, the program either loops continuously or returns to the calling program, depending on the state of the return flag found in location \$FF. If bit 3 is one, a character is waiting at the input port, and the character is then read from the read register (RDREG) of the 6551.

The DEMO portion of this program calls the INIT routine, and sends each letter of the alphabet to the connected device. After each character is sent, the program waits to see if a response has been received from the external device. If a character is waiting, the program ends.

#### Assembly Language Source Code Demo

-----  
Here is a demo of accessing the Super Serial Card with Assembly Language.

```

## A/UX: AppleShare Server Support (6/93)

Revised: 8/12/93  
Security: Everyone

A/UX: AppleShare Server Support (6/93)

=====  
Article Created: 29 August 1989  
Article Reviewed/Updated: 6 June 1993

TOPIC -----

Is it possible to run the AppleShare File Server under A/UX, so that the Macintosh II running it can act as a server and as a UNIX user workstation at the same time?

DISCUSSION -----

The answer depends on what software versions you're running.

A/UX 1.1 did not support the AppleShare 2.0 Server software. However, you can turn an A/UX system into an "AppleShare" server through the use of AUFS from Columbia University or uShare from Information Presentation Technologies. Either of these products runs on under A/UX, turning it into a server supporting AppleShare clients. Also, they do not require a dedicated system.

If you're have the Apple Work Server (AWS) 95, running A/UX 3.0.1 you can. You can also run FileShare under System 7.x.

Article Change History:

## System 6.0.3: Incompatible with Macintosh 512Ke and HD20

Revised: 9/22/89  
Security: Everyone

System 6.0.3: Incompatible with Macintosh 512Ke and HD20

=====

This article last reviewed: 14 September 1989

Macintosh 512Ke users (some also running HD-20s have reported the following scenario:

After updating the System on the startup hard disk to System 6.0.3, the system would not start. Attempts to start up from a startup disk with System 6.0.3 gave the same symptoms. That is, the Happy Macintosh face appears. Then, the dialog box appears and stays blank. At that point, the system hangs. Restarting from a System 6.0.1 floppy works.

There are a couple of thing that could cause this lack of compatibility. One is the lack of support for the HD-20, which was dropped with System 6.0. Another is that System 6.0.3 requires XPRAM (256 bytes versus 20 bytes) in the Macintosh. A Macintosh Plus does not have XPRAM, and System 6.0.3 relies on it. This is probably the reason the Macintosh 512Ke hangs when starting up. It is looking for information from XPRAM and cannot find it. Starting up from an HD-20 may be compounding the problem.

According to the System Software manual that came with System 6.0, the latest version of system software recommended for a Macintosh 512Ke is System 4.1, Finder 5.5. It doesn't seem to matter whether an HD-20 is in use or not. Macintosh 512Ke users would do well to re-install Finder 5.5 and System 4.1 on their machines.

## Motorola CDX268: Terminal Emulation for Macintosh or Apple II

Revised: 9/22/89  
Security: Everyone

Motorola CDX268: Terminal Emulation for Macintosh or Apple II

=====

This article last reviewed: 26 May 1989

Emulating a Motorola CDX268 terminal on a Macintosh or Apple II is easy. The CDX286 is what was once, affectionately, called a "glass TTY". It's a very basic terminal that you can configure for baud rate, data and stop bits, and parity. The port can be configured for either RS-232 or RS-422. It requires no strange or out-of-the-ordinary protocols. All of this means that almost any terminal emulation program for the Macintosh or Apple II can be set up to act like a CDX268.

To do the emulation, set it up CDX286 in TTy mode and connect the appropriate cable to the built-in serial port. The cable, like your configuration, depends on what you're connecting to.

## Macintosh II: Color Picker and Exact Color Match Issue

Revised: 7/8/92  
Security: Everyone

Macintosh II: Color Picker and Exact Color Match Issue

=====

Article Created: 26 May 1989  
Article Last Reviewed: 7 July 1992  
Article Last Updated:

TOPIC -----

If you have a 4-bit color card in your Macintosh, you may have noticed that the Color Picker displays the entire range of over 16 million colors in the top-half of the color box to the left of the color wheel (inside the color window). However, when you choose color, the actual color is some ugly approximation. This anomaly rests with the Color Picker and the device's Color Look-Up Table (CLUT).

DISCUSSION -----

The Color Picker Package is a tool that presents a standard interface for color selection. With this dialog, any application can ask the user to choose a color. The Color Picker displays all 16.8 million colors available through Color QuickDraw. They are the colors that are available to any color device, regardless of the number of bits that device can display. A 4-bit color card can display only 16 of the 16.8 million different colors at one time. An 8-bit color card can display 256 of the 16.8 million colors at one time. The number of bits that the card has does not limit the number of colors that are available to be shown, but rather it limits the number of colors that the device can show at one time.

The Color Picker returns the RGB color value of the chosen color to the application to do with it what it wants. The application has the choice of going to the device's Color Look-Up Table (CLUT) and approximating the color by picking the color closest to the chosen color, or replacing an entry in the device's CLUT to show the exact color picked. The Color Picker, itself, displays the exact color by borrowing a color table entry from the CLUT and changing it according to the color selected. When it's done, it puts everything back to the way it was. Thus, when you quit the

Color Picker, the CLUT is the same as when Color Picker was called.

The choice of showing the exact color or an approximation is entirely up to the application. The Color Picker is not aware of the colors available in the CLUT, nor does it care. There may be more than one device that the application wants to display color on. In such a case, the CLUT for each of these devices will probably be different. This gives the application the ability to save the RGB color values returned from Color Picker and display a more or less accurate approximation of that color, depending upon the device used.

## AppleShare Workstation: How to Install It on the Mac SE/30

Revised: 9/22/89  
Security: Everyone

AppleShare Workstation: How to Install It on the Mac SE/30

=====

This article last reviewed: 24 August 1989

Users have had problems installing AppleShare workstation software (release 2.0 is the most common version) on a Macintosh SE/30. For example, after initializing the hard disk on the Macintosh SE/30 and installing System software 6.0.3, they experienced problems installing AppleShare Workstation software. To wit, after installing AppleShare Workstation software and selecting Shut Down, the system hangs with a frozen screen.

When they reinstalled the System software using Minimum Macintosh SE/30, the AppleShare Workstation software worked. Shut Down worked too, although it seemed to take slightly longer. This type of thing can occur if the AppleShare Workstation software was installed from a disk using System software 6.0.2.

To have everything properly installed, do the following:

- 1) Use Macintosh System Tools disk, version 6.0.3, to install the System software.
- 2) Use the Macintosh Utilities Disk 1 disk, version 6.0.3, to install the AppleShare Workstation software.

Both disks are a part of the System software 6.0.3 four-disk set sent with the Macintosh SE/30. Each disk has an Installer and Installer scripts (full system scripts on the Tools disk and minimum system and workstation on the Utilities disk).

## LocalTalk PC Card: Keyboard Problem in PS/2

Revised: 9/22/89  
Security: Everyone

LocalTalk PC Card: Keyboard Problem in PS/2

=====

This article last reviewed: 28 August 1989

TOPIC -----

While attached to the AppleTalk network, the cursor arrows, instead of moving the cursor, displays the corresponding numeric keypad number (8, 4, 6, or 2). This is intermittent. That is, when they hold down the right arrow key, the cursor moves along the screen and then, suddenly, a "6" appears. Also, some typed characters appear in caps, as if the Shift key was pressed.

Yet, when the LocalTalk PC Card is removed, WordPerfect works fine.

Setup: PS/2 30, running InBox 2.2 and AppleShare 2.0., with a LocalTalk PC Card in it running WordPerfect 4.2 (non-network version).

DISCUSSION -----

Although the Token Ring card is currently not connected, having it in the machine can cause hardware conflicts between it and the LocalTalk PC Card. Check to make sure that the two cards are not using the same IRQ (interrupt) line. Also make sure that the two cards are not using the same DMA channel. A quick way to check if the two cards are in conflict is to remove the Token Ring card. Does the problem goes away?

Another possibility is that the LocalTalk PC Card has gone bad. If you have access to another LocalTalk PC Card, try that card to see if you get the same results.

While you are checking for DMA and IRQ conflicts between the two network cards, also should check the rest of the hardware in the machine for the possibility of such conflicts. For instance, multiple serial ports could cause conflicts with the IRQ line, which is the default on the LocalTalk PC Card.

## CCITT Group 4: Macintosh Compatibility

Revised: 4/3/90  
Security: Everyone

CCITT Group 4: Macintosh Compatibility

=====

This article last reviewed: 28 August 1989

TOPIC -----

A am in the process of creating a company-wide database on a 3070 mainframe to store images. I have decided on CCITT Group 4 as the format for these images. To use Macintoshes with this system, I need Group 4 compatibility. Does Apple have such a thing, or is this support available from a third party?

DISCUSSION -----

CCITT Group 4 classification is not a format, but rather a classification of facsimile machines for document transmission over the public networks. Groups 1, 2, and 3 are for use over the public telephone network. Group 4 is for use over the public data networks, which also may include the public telephone network. In other words, Group 4 does everything the other groups do, plus more. It specifically incorporates means for reducing the redundant information in the document prior to transmission and assuring essentially error-free reception of the document.

It is important to understand that CCITT Group 4 is not a format. It is many pages of specifications that explain exactly how an apparatus of this grouping works. It specifies the binary description of the document.

As of August, 1989, Tech Comm did not know of any application or utility for the Macintosh that is CCITT Group 4-compatible.

## Canvas 2.0: LaserWriter Printing Problem

Revised: 9/22/89  
Security: Everyone

Canvas 2.0: LaserWriter Printing Problem

=====

This article last reviewed: 28 August 1989

TOPIC -----

I have a problem when overlaying two objects in Canvas 2.0. According to Deneba Software, this is a known problem with the LaserWriter ROMs that has to do with an exclusive-or command. Has this known problem been fixed with the LaserWriter Rev 47 ROMs?

DISCUSSION -----

No, the problem remains. Tech Comm recreated the problem with the 2.0 ROMs (Rev 38 of PostScript) and with the 3.0 ROMs (Rev 47 of PostScript) on a LaserWriter Plus and on a LaserWriter IINT.

## LaserWriter: How To Send Asynchronous PostScript File

Revised: 9/22/89  
Security: Everyone

LaserWriter: How To Send Asynchronous PostScript File

=====

Article Created: 28 August 1989  
Article Last Reviewed: 15 July 1992  
Article Last Updated: 15 July 1992

### TOPIC -----

How can I send a PostScript file, produced with the Command-K combination (under System 6.x) or by clicking the "Postscript File" destination in the Print dialog (under System 7), to a LaserWriter using asynchronous file transfer? I've been unsuccessful using "Send File..." from MacTerminal and others. I can send the file successfully using SendPS over AppleTalk, but I get a PostScript error when I send the same file using a 9600-baud asynchronous connection. It appears that XON/XOFF doesn't properly control the flow. What am I missing?

### DISCUSSION -----

The use of Command-K (under System 6.x), or using the "Postscript File" destination option in the Print dialog (under System 7) to create a PostScript file actually adds the information from Laser Prep to the beginning of the file being generated. This eliminates the need to send the Laser Prep header separately. In fact, there is a chance that the problem is being caused because the header is being included.

There is a segment of PostScript included in Laser Prep header that checks to see if certain routines are already loaded in the LaserWriter RAM. If they are, everything from that point in the header to the next Control-D character is deleted from the print job. Unfortunately, when the header is added to the PostScript file, no Control-D is appended at the end of the header information. Therefore, the next Control-D reached is the end of the file, which effectively flushes the job by deleting everything but the header.

Solution

-----

- 1) Using a blank document, generate a PostScript file, which contains the header, by (under System 6.x) holding down Command-K when you select the OK button in the Print dialog box, or by (under System 7) clicking the "Postscript File" radio button in the Print dialog. This generates the header only. Send this file to the LaserWriter. You must do this once per power-on cycle of the LaserWriter, unless you need to switch headers.
  
- 2) When you are creating files from documents that you want printed, hold down Command-F (under System 6.x) when you select the OK button in the print dialog box. This generates a PostScript file without the Laser Prep header. Because you already have sent the header, the necessary dictionary is already loaded, and your files should print properly. Unfortunately, to generate a PostScript file without the Laser Prep header in System 7, you need a shareware program like Trimmer, which gives the option of stripping the header from an existing PostScript file.

## MPW 3.0: Conflicts Caused by INITs Misusing PBHSetVol

Revised: 9/22/89  
Security: Everyone

MPW 3.0: Conflicts Caused by INITs Misusing PBHSetVol

=====

This article last reviewed: 28 August 1989

TOPIC -----

Apple Tech Comm has found a problem in a number of third-party INITs that cause the MPW Installer to fail. This problem is the result of these products doing a HSetVol by calling PBHSetVol. Macintosh Technical Note 140, "Why PBHSetVol is Dangerous," warns against using PBHSetVol. This problem has been reported most frequently with TOPS from TOPS, a Sun Microsystems Company.

DISCUSSION -----

When you try to run the MPW Installer while running a third-party INIT, you get an error saying the "DoIt" script cannot be found. The message appears when an INIT uses PBHGetVol to get and save the working directory and then tries to restore the working directory using PBHSetVol. The result is that such an INIT sets the working directory to the root of the volume containing the installation volume. Note: Any mention of installation in this article refers to the procedure outlined in the "Macintosh Programmer's Workshop Development Environment Reference, Volume 1." Here are three workarounds for this problem.

First, you can install MPW by hand and forego the MPW Installer. However, this does not stop problems caused by INITs that use PBHSetVol. Any INIT that uses PBHSetVol interferes with the setting of the working directory any time you insert a disk while running MPW. After inserting a disk, the problem manifests itself when:

- MPW tries to access a script in the current directory.
- A tool tries to open a file in the current directory.

In both of these cases, a "directory :" command (as given in step 2 below) restores your environment.

Second, you can install MPW without the INIT running. In the case of TOPS,

restart while holding down the Command key. During the restart process, TOPS will bring up a dialog asking if you want to install TOPS. Answer no, and proceed to install MPW 3.0.

Third, you can modify the installation script by following the procedure described below:

- 1) Open up the file "Startup" in the Installation Folder using any editor that can read text files.
- 2) Search for the line: "DoIt copyStuff >= errorFile" and insert the line "directory :" immediately before it. This forces the MPW Shell to reset the working directory to Installation Folder before running the "DoIt" script.
- 3) Save the "Startup" file and then do the installation procedure outlined in the "Macintosh Programmer's Workshop Development Environment Reference, Volume 1."

HyperCard: Information on ADSP XCMDs in MacTutor

=====

Article Created: 30 August 1989  
Article Reviewed/Updated: 22 July 1993

TOPIC -----

I need to do HyperCard AppleTalk-type developing. My project requires data streaming and zones, but the current HyperAppleTalk Toolkit does not support ADSP (Apple Data Stream Protocol). Will the toolkit be updated to provide this support? If not, where can I get more information on writing my own XCMDs and XFCNs?

DISCUSSION -----

Apple is not planning any updates to the package. However, "Inside Macintosh" contains all the information you need to create the kind of XCMDs you require. Further, the author of the toolkit XCMDs wrote a series of articles in "MacTutor" (publication now known as MachTech) magazine describing AppleTalk XCMDs including ADSP. The articles are an excellent source of information on how it all works. The series ran from January through May of 1989.

Macintosh Compatible Hand-Held Scanners and Bar Code Readers

=====

Article Created: 30 August 1989  
Article Reviewed/Updated: 26 July 1993

TOPIC -----

I need a light pen for the Macintosh (NuBus or ADB).

DISCUSSION -----

We have listed examples of four different types of "light pen input devices" or related devices.

### Fixed-Position Bar-Code Readers

-----

- UNi Bar Code Reader from TPS Electronics, connects via the keyboard or ADB port
- Datapen from Datalogic, Inc., connects via the keyboard

### Portable Bar-Code Readers

-----

- TimeWand from Videx, Inc. (a serial device requiring serial download through a communications program which is available from Videx.)
- XP-300 Portable Bar Code Reader from TPS Electronics, a portable, serial device.

### Hand-Held Scanners

-----

- LightningScan from Thunderware, Inc. A hand-held scanner capable of handling images up to 4 inches wide; interfaces to any Macintosh SCSI port.
- ScanMan for Macintosh from Logitech, Inc. A hand-held scanner capable of handling images up to 4.1 inches wide; interfaces to any Macintosh SCSI port.

Touch Screen

-----

Mac 'N Touch from MicroTouch Systems, Inc.

Macintosh II, IIfx & IIfx: Auto-Power-On Device

=====  
Article Created: 30 August 1989  
Article Last Reviewed: 21 July 1992  
Article Last Updated: 24 July 1992

TOPIC -----

I need a device that can automatically start a Macintosh II (or Macintosh IIfx and IIfx) following a power outage and that can start the computer at a specified time.

DISCUSSION -----

The only solution we know of is a NuBus card called MacClock II from MacSema. MacClock II contains a real-time clock with battery. It also restarts the computer when power is applied to the electrical circuit (as would be the case when power comes back on after an outage). MacClock II also starts a Macintosh system at a specified time and can execute macros via programs like Tempo II and QuicKeys.

## Apple IIGS Super-High-Res Graphics: Access from BASIC

Revised: 10/29/90  
Security: Everyone

Apple IIGS Super-High-Res Graphics: Access from BASIC

=====

This article last reviewed: 25 October 1990

TOPIC -----

Are there any Applesoft BASIC commands to invoke super-high-resolution graphics on an Apple IIGS?

DISCUSSION -----

The super-high-resolution graphics of the Apple IIGS are not directly available from Applesoft. Applesoft BASIC supports only the original Apple II low-resolution graphics (40x48 or 40x40 with 4 lines of text) and high-resolution graphics (280x192 or 280x160 with 4 lines of text).

One solution is "Iconix IIGS" from So What Software. This is a set of machine language subroutines accessible from Applesoft. They provide an interface to the super-high-resolution graphics mode of the Apple IIGS.

Other BASIC solutions for super-high-resolution graphics mode include Complete BASIC Compiler from Complete Technologies, AC/BASIC from Absoft Corporation, and Micol Advanced BASIC from Micol Systems.

The Complete BASIC Compiler is similar to Apple's GSBASIC (available from APDA) with the addition of graphics support. AC/BASIC is compatible with Microsoft's QuickBASIC language and provides graphics support similar to what is found in QuickBASIC for the Macintosh. Micol Advanced BASIC is modeled after Applesoft. Anyone familiar with Applesoft should be comfortable with Advanced BASIC.

GSBASIC from APDA provides calls to QuickDraw II. However, GSBASIC does not directly support graphics commands within the BASIC language syntax.

For more details, search the Tech Info Library under "So What Software", "Complete Technologies", "Absoft Corp", and "Micol Systems".

## System 6.0.X: Not Compatible with Macintosh 512Ke

Revised: 9/22/89  
Security: Everyone

System 6.0.X: Not Compatible with Macintosh 512Ke

=====

This article last reviewed: 5 September 1989

TOPIC -----

Has Apple determined if a Macintosh 512Ke can be used with System Software 6.0.3? I have a Macintosh 512Ke with a third-party 2MB memory upgrade. I cannot start the system with either System 6.0.2 or System 6.0.3.

DISCUSSION -----

Officially, System 6.0 and later were not designed, tested, or recommended for Macintosh systems prior to the Macintosh Plus. The total memory installed in the system is irrelevant. The fact that the Macintosh Plus and later Macintosh computers have 256 bytes of PRAM is a major part of the compatibility problem. This is Apple's official position.

## Apple Portrait Display: Macintosh SE Card

Revised: 10/22/90  
Security: Everyone

Apple Portrait Display: Macintosh SE Card

=====

This article last reviewed: 5 September 1989

TOPIC -----

Does anyone make a card to connect the Apple Portrait Display to a Macintosh SE?

DISCUSSION -----

RasterOps makes a card called the Clearview APD for the Macintosh SE that drives an Apple Portrait Display. The board is also an accelerator running a 68000 at 16 MHz. Includes a socket for a 68881 math coprocessor. ("APD" stands for "Apple Portrait Display.")

For more information, search on "RasterOps" in the Tech Info library.

Sony GDM-1601 and 1602 Monitors: Incompatible With Macintosh

=====

This article last reviewed: 5 September 1989

TOPIC -----

How can I connect large a Sony GDM-1601 monitor to my Macintosh? What about the Sony GDM-1602?

DISCUSSION -----

The Sony GDM-1601 and Sony GDM-1602 monitors are not compatible with the Macintosh 1-bit, 4-bit, or 8-bit video cards. These monitors may be compatible with video cards from companies like RasterOps, Radius, or SuperMac Technologies. Check with them for more information. (For more details, search the Tech Info Library under "RasterOps", "Radius", and "SuperMac".

The primary difference between the two displays is that the Sony GDM-1601 has a display resolution of 1280 x 1024, while the Sony GDM-1602 has a display resolution of 1024 x 768.

## Apple FDHD: Formatting PS/2 720K Disks in 1.44 Drives

Revised: 9/22/89  
Security: Everyone

Apple FDHD: Formatting PS/2 720K Disks in 1.44 Drives

=====

This article last reviewed: 14 September 1989

TOPIC -----

- 1) PS/2 machines with 1.44MB drives will, by default, initialize double-sided dual-density disks to the 1.44MB format when the unsuspecting user simply types FORMAT A:.
- 2) IBM recommends against this and refers the user to the MS-DOS documentation for the proper arcane FORMAT options needed to properly format double-sided dual-density disks.
- 3) Most users don't know about any of this and use FORMAT A: just like they used to.
- 4) Entire departments are, therefore, evolving collections of double-sided dual-density disks that are readable on PS/2 machines and unreadable on Macintoshes (so much for data exchange).
- 5) Apple's choices are clear:
  - a) Embark on a massive PS/2 user education program.
  - b) Make a "best effort" try to read the disks (possibly with an informative alert).

RESPONSE -----

This is not a problem with AFE. Apple designed the drive to work properly, and it looks for the "bonus hole" to determine whether a disk is high-density. The drive design will not be changed.

Installations with PS/2 machines should make an effort to educate users in proper way to format disks instead of trying to find a patch and jeopardize their data integrity.

The command to format a DOS disk as 720K in a 1.44MB drive is:

FORMAT A:/N:9/T:80

## Macintosh-to-VAX Connectivity and Tunneling

Revised: 9/22/89  
Security: Everyone

Macintosh-to-VAX Connectivity and "Tunneling"

=====

This article last reviewed: 5 September 1989

TOPIC -----

I am evaluating AlisaShare/Macintosh-to-VAX connectivity. This system will consist of a HyperCard front end that, based on selections made by the user (for example, clicking on a series of buttons), downloads a number of Microsoft Word files from the AlisaShare volume and then merges them together into a single document. The front end is running smoothly.

The goal of this project is to have all of the components of the proposal system (for example, the individual premerge Microsoft Word documents) sitting on a hub VAX at the corporate site. Smaller VAX systems at each remote field location are connected to the VAX using DECnet. The Macintoshes, on which the HyperCard front end will run, are then attached to these local VAX systems through a router (either a FastPath 4 or an Apple Internet Router). I know that the ability to "tunnel" AppleTalk protocols through DECnet is on the way, but I need a solution now.

- 1) Do I need to be concerned about tunneling AppleTalk through DECnet, or can the Macintoshes access the VAX at the corporate site directly through the Ethernet?
- 2) Will AppleTalk Phase 2 be necessary? If so, when can I anticipate Phase 2 for VMS?

DISCUSSION -----

If the remote sites are connected to the hub site via Ethernet bridges, you do not need to use DECnet "tunneling" as long as the bridges pass the AppleTalk packets. On the other hand, if the VAX systems function as half bridges with bridge processes on one communicating with other bridge processes using DECnet as the link between them, "tunneling" is required.

"Tunneling" is available for AppleTalk for VMS 2.0. You do not have to wait

## ..TIL04462-Macintosh-to-VAX\_Connectivity\_and\_Tunneling.pdf

for AppleTalk Phase 2. However, you should be aware of some possible "tunneling" problems with AppleTalk for VMS 2.0. These problems are documented in the Tech Info Library. Search on "tunneling".

## Token Ring Network: Model 5 Capabilities for Macintosh

Revised: 9/22/89  
Security: Everyone

Token Ring Network: Model 5 Capabilities for Macintosh

=====

This article last reviewed: 5 September 1989

TOPIC -----

I have an IBM 3090 and a 3x74 controller with a Token Ring Interface Coupler (TIC). Attached to the TIC is a Compaq AT serving as a dedicated gateway. The gateway machine contains a Token Ring card and is running IBM's Token Ring support driver, Novell NetBIOS, and Attachmate Extra! 3270 Gateway software.

The gateway also contains a 3COM Ethernet card for attaching Ethernet workstations. I want to attach Macintoshes to this network, but I need to have the Model 5 extended attributes and DFT capabilities. Attachmate currently does not have a solution for this.

Is there a way to attach Macintoshes to this network and get these capabilities through their gateway (as with the Internet Router), or should I use something like a Netway 1000?

DISCUSSION -----

We are not sure which network you want to attach the Macintoshes to. If you connect the Macintoshes to the Token Ring network, MacDFT over the TokenTalk NB Card is a solution for you. It supports Model 5 capabilities with all the extended attributes you mentioned.

As of July 1989, we don't know of a terminal emulation solution for attaching your Macintoshes directly to the Ethernet network. The Netway 1000 supports only LocalTalk cabling.

## MacTCP: Questions and Answers

Revised: 11/29/95  
Security: Everyone

MacTCP: Questions and Answers

=====

Article Created: 22 September 1989  
Article Reviewed/Updated: 29 November 1995

TOPIC -----

Here are a few questions on Apple's TCP/IP functionality. In all cases, I am assuming the use of Apple's MacTCP software.

- 1) Do the PD programs, like NCSA, support Macintosh-to-Macintosh FTP over LocalTalk and/or EtherTalk?
- 2) Are there any problems using MacTCP-based products with EtherTalk Phase 2 (due to the change from Ethernet to 802.3 framing)?
- 3) Can I run MacTCP sessions concurrently with AppleTalk sessions over the same physical media?
- 4) Can I run MacTCP sessions concurrently with AppleTalk sessions over different physical media (for example, AppleTalk on LocalTalk concurrent with TCP/IP over Ethernet on the same Macintosh)?

DISCUSSION -----

1) Question: Do the PD programs, like NCSA, support Macintosh-to-Macintosh FTP over LocalTalk and/or EtherTalk?

Answer: NCSA does NOT support Macintosh-to-Macintosh FTP over LocalTalk or Ethernet cabling.

2) Question: Are there any problems using MacTCP-based products with EtherTalk Phase 2 (due to the change from Ethernet to 802.3 framing)?

Answer: There should not be any problems regarding framing when using MacTCP-based products with EtherTalk Phase 2. MacTCP is co-resident with AppleTalk protocols so there can be concurrent TCP/IP and AppleTalk operations. EtherTalk

manages data flow so it can co-exist on Ethernet cable with TCP/IP protocols.

3) Question: Can I run MacTCP sessions concurrently with AppleTalk sessions over the same physical media?

Answer: Yes, for the same reason as (2). For example, MacTCP can be run while a print job goes to an Apple LaserWriter printer over LocalTalk cabling.

4) Question: Can I run MacTCP sessions concurrently with AppleTalk sessions over different physical media (for example, AppleTalk on LocalTalk concurrent with TCP/IP over Ethernet on the same Macintosh)?

Answer: AppleTalk and MacTCP can run over the same media, or one protocol can run over one medium while the other protocol runs over a different medium.

## SMB File Utility: Difficulties Over Ethernet

Revised: 10/4/89  
Security: Everyone

SMB File Utility: Difficulties Over Ethernet

=====

This article last reviewed: 5 September 1989

TOPIC -----

I am running PC LAN over Ethernet cabling and would like to access a PC LAN file server from an Ethernet connected Macintosh. Can I use the SMB File Utility over Ethernet? Or, is it strictly a Token Ring situation?

DISCUSSION -----

While the SMB protocols are not limited to running on Token Ring, they are usually thought of in conjunction with Token Ring. Because Apple SMB File Transfer Utility works so closely with the Texas Instrument Token Ring interface controller chip set on the TokenTalk NB Card, it would be difficult to port to an Ethernet environment without a major rewrite of the software.

For file transfer and sharing in a PC/Macintosh environment over Ethernet, try an AppleTalk Filing Protocol Server solution, like Novell's NetWare or even AppleShare.

## TokenTalk 2.0: Token Ring and Source Routing Bridges

Revised: 9/22/89  
Security: Everyone

TokenTalk 2.0: Token Ring and Source Routing Bridges

=====

This article last reviewed: 6 September 1989

TOPIC -----

A client resides on a 4MB Token Ring called A. The server is on a 4MB Token Ring called B. Connecting the two rings is a 16MB fiber backbone, and at either end of each sub ring A and B is an IBM bridge. Can we pass our AppleTalk packets through these bridges?

DISCUSSION -----

The TokenTalk 2.0 software works in Token Ring environments where two or more Token Ring networks are bridged together with source routing bridges.

For more information on TokenTalk 2.0 software and source routing bridges, please refer to the "LAN Minds" and "MacDecathLAN" training materials.

## A/UX: NFS Not a directory Message (9/94)

Revised: 9/7/94  
Security: Everyone

A/UX: NFS "Not a directory" Message (9/94)

=====

Article Created: 22 September 1989  
Article Reviewed/Updated: 6 September 1994

TOPIC -----

I have some problems with an nfs configuration. Here is what happens:

```
#mount
/dev/dsk/c5d0s0 on / type 5.2 (rw,noquota)

#ls -la /udd/halles
total 2
drwxrwxrwx  2 root    root      32 Jan 12 06:40 ./
drwxrwxrwx  6 root    root      96 Jan 12 06:40 ../
```

```
#mount ilog:/udd/halles /udd/halles
#mount
/dev/dsk/c5d0s0 on / type 5.2 (rw,noquota)
ilog:/udd/halles on /udd/halles type nfs (rw)
```

To prove the exchange of information, the command df:

```
#df
/                /dev/dsk/c5d0s0      7064 blocks    9443 i-nodes
/udd/halles ilog:/udd/halles  1514 blocks     0 i-nodes
```

It runs, and ls runs, too (the permissions are the remote permissions).

```
#ls -l /udd
drwxrwxrwx  6 root    root      96 Jan 12 06:40 ./
drwxr-xr-x 17 root    root     720 Jan 12 07:17 ../
drwxrwxrwx  2 root    root      32 Jan 12 06:40 chatelet/
drwxrwxrwx  2 root    root      32 Jan 12 06:40 cite/
drwxr-xr-x 61 root    ilog    1536 Jul  3 1989 halles/
```

Now the problem:

```
#cd /udd/halles
/udd/halles : Not a directory
```

I run a command like `ls /udd/halles`, and I get a list of the subdirectory with the error message: `<dir> : Not a directory`.

#### DISCUSSION -----

As you described, there doesn't seem to be anything wrong on your local NFS client side. However, from the error message "Not a directory", it sounds like the REMOTE NFS server exported filesystem or directory, `/udd/halles` in this case, is not a directory type.

Check the spelling of the exported directories on the remote NFS server; both the exported entries in the `/etc/exports` file and the actual filesystem object MUST be a directories. After checking the spelling from the remote NFS server, at the local NFS client do `/etc/umount /udd/halles`, and try the NFS mount command again.

Also the `"showmount [a] [d] [e] [host]"` is a nice tool for NFS to display things like directories that have been mounted by clients, the list of exported filesystems from the server, and so on. See `showmount (1M)` for details.

## Apple II Network: Drop Box Creation From Finder Only

Revised: 9/22/89  
Security: Everyone

Apple II Network: Drop Box Creation From Finder Only

=====

This article last reviewed: 6 September 1989

TOPIC -----

I work on an AppleShare/Aristotle network setup. I created a Drop Box on the server, so that users can save their AppleWorks files directly into the Drop Box on the server by using the appropriate ProDOS pathname. It doesn't work! (Owner has all privileges, everyone else has Make Changes only.)

I first tested this on a Macintosh workstation, trying to save a document to a Drop Box using the "Save As" command. Drop Boxes are dimmed in the dialog box, so I wasn't able to open the Drop Box folder and save the document. The only alternative I could think of was to save the document somewhere else, return to the Finder, and then drag the document into the Drop Box.

Are there any alternatives for Apple II users who want to use Drop Boxes?

DISCUSSION -----

The Finder is the only mechanism we are aware of that lets you put files into a Drop Box folder.

## AppleTalk Phase 2: Network Numbers, Nodes, and Zones

Revised: 7/10/91  
Security: Everyone

AppleTalk Phase 2: Network Numbers, Nodes, and Zones

=====

Article Created: 6 September 1989  
Article Last Reviewed: 8 July 1991  
Article Last Updated: 8 July 1991

TOPIC -----

I have some questions about AppleTalk Phase 2. The material I have read states that AppleTalk Phase 2 will provide for:

- 1) 65,534 possible network numbers
- 2) 16 million nodes
- 3) 256 zones per network
- 4) 1,024 networks per Internet

How were these numbers arrived at?

DISCUSSION -----

- 1) Network numbers are defined by a 16-bit number:  $2^{16} = 65,536$ . The network number 0 is reserved to mean unknown, and network number 65,535 is reserved for future use. This means a total of 65,534 networks are possible.
- 2) AppleTalk Phase 1 supported  $2^8$  nodes minus the reserved nodes, ID 0 and ID 255, which resulted in a total 254 nodes possible. AppleTalk Phase 2 nodes on the physical network are identified by their virtual network number and their 8-bit node ID. The node IDs of 0, 254, and 255 are reserved in AppleTalk Phase 2.

Because it is possible to have 65,534 networks with 253 nodes in each network, it is possible to have a maximum of 16,580,102 nodes ( $65,534 * 253 = 16,580,102$ ). Note: Network numbers 65,280 through 65,534 are used only when a router is not present.

- 3) Actually, the maximum number of physical zones per network is 255. This is

an architectural limitation of AppleTalk Phase 2. The AppleTalk Internet Router supports a maximum of 255 names on a single zone list. The reason for 255 is because the zone list may apply to a single physical network.

Also, an AppleTalk Phase 2 internet (1 or more physical networks connected together via routers) is capable of supporting more than 256 zones. But the AppleTalk Internet Routers supports a maximum of 256 zones on an internet.

- 4) There can be a maximum of 1,024 entries in the routing table for the AppleTalk Internet Router. Each entry can refer to an individual network number or a range of network numbers. This limitation is not AppleTalk Phase 2-specific.

## Macintosh IIci: General Description (Discontinued)

Revised: 6/1/94  
Security: Everyone

Macintosh IIci: General Description (Discontinued)

=====

Article Created: 18 September 1989  
Article Last Reviewed: 8 July 1992  
Article Last Updated: 8 July 1992

TOPIC -----

This article describes the Macintosh IIci.

DISCUSSION -----

The Macintosh IIci is an improved Macintosh IICx that offers higher performance and enhanced functionality. Features offered by the IIci that are not available on the IICx include:

- A 25 MHz Motorola MC68030 microprocessor and a MC68882 numerics coprocessor.
- A Built-In Video connector that allows IIci users to connect specific Apple monitors to a IIci without requiring the use of a NuBus video card. Monitors supported by Built-In video include:
  - + Apple High-Resolution Monochrome Monitor at 2, 4, 16 and 256 grays
  - + AppleColor High-Resolution RGB Monitor at 2, 4, 16 and 256 colors/grays
  - + Apple Macintosh Portrait Display at 2, 4 and 16 grays
- A cache connector that supports the use of an optional high-speed cache card.
- RAM Parity error detection is offered in IIci parity configurations that customers can special order.

Features that are common to the IIci and IICx include:

- Support for one internal 1440K Apple SuperDrive (formerly Apple FDHD) and an external drive port for one external Apple SuperDrive
- Support for one internal 3 1/2" SCSI hard disk, and an external SCSI port for additional SCSI devices.
- Three NuBus system expansion slots

- Two serial ports
- One stereo sound port
- Two ADB ports

#### UPGRADES

For those those who wish to upgrade their Macintosh IICx units upgrade to a Macintosh IIci units, upgrades will be offered. This upgrade will include a new logic board, a new bottom chasis, 1 MB of DRAM, Macintosh system software 6.0.4, HyperCard 1.2.5, and IIci manuals. (NOTE: Parity upgrades, IICx to parity IIci or non-parity IIci to parity IIci, will not be offered.)

#### MC68030

The Macintosh IIci uses the Motorola MC68030 at 25 MHz. The CPU speed for previous members of the Macintosh II family has been 15.6672 MHz. Also, 68030 burst reads to the on-chip data and instruction caches are supported in the IIci to further increase performance. The MC68030 is Motorola's second-generation 32-bit microprocessor, and combines a central processing unit, a data cache, an instruction cache, an enhanced bus controller (NOT the NuBus controller), and a memory management unit into a single VLSI device. Internal function blocks of the microprocessor are designed to operate in parallel, allowing instruction execution to overlap.

The MC68030 integrates the functionality of the MC68020 32-bit microprocessor with a subset of the MC68851 Paged Memory Management Unit (PMMU). Commonly called the 030 (pronounced "oh-three-oh"), the MC68030 is compatible with Macintosh IIX timing and software.

#### MC68882

The MC68882 numerics coprocessor (also called the Floating Point Unit, or FPU) provides high speed, extremely accurate, floating-point computation to IEEE standards.

The processor operates in parallel with the MC68030 and is clocked at 25 MHz. The FPU speed for previous members of the Macintosh II family has been 15.6672 MHz. Calls to the Apple SANE routines will use the MC68882. The MC68882, also called the 882 (pronounced "eight-eighty two").

Both processors use the same base instruction set--the major advantage of the MC68882 is increased speed. With the MC68882, you can perform both memory moves and chip operations in parallel--as long as they don't conflict.

#### Memory Management

Macintosh IIci can support the A/UX operating system without adding the PMMU, thanks to on-chip memory management by the MC68030. The MC68030 allows true 32-bit address translation with hardware page replacement. The built-in memory unit is also capable of ignoring the high 8-bits of the

address to allow Macintosh software to run in 24-bit mode.

(NOTE: The MC68030 PMMU is a subset of the MC68851 PMMU, rather than an exact replacement.)

## Macintosh IIfx Cache Card

The Macintosh IIfx Cache Card includes 32K of 25-nanosecond static RAM. With a IIfx Cache Card installed, system performance is increased by 20 to 30 percent. As of September 1, 1991 all Macintosh IIfx computers include the Apple Macintosh IIfx Cache Card.

## Apple SuperDrive

The SuperDrive can read from and write to any of the major 3.5-inch disk formats, including Macintosh (GCR 400K, 800K, and MFM 1.44MB), Apple II (800K), MS-DOS and OS/2 (MFM 720 and 1.44MB).

GCR stands for Group Code Recording; MFM stands for Modified Frequency Modulation. MFM and GCR only effect how the bits are placed on the disk, not the directory structure. The drive is supported by the SWIM (Sander, Woz Integrated Machine) chip.

(NOTE: There is special 1.44MB media that should NOT be used in the older 400K or 800K drives.)

## SWIM Chip

The SWIM chip is a single-chip combination MFM/GCR controller for internal and external floppy drives. It was designed for the SuperDrive, but is compatible with the current 400K and 800K drives. The SWIM chip replaces the IWM chip, and is pin- and function-compatible with that device.

## Logic Board ROM and ROM SIMM

The Macintosh IIfx comes with 512K of ROM, which is soldered to the logic board. For update and upgrade purposes, the IIfx logic board has a ROM SIMM slot. When the ROMs in a IIfx unit are updated or upgraded, a ROM SIMM card with the new ROM chips is placed in the SIMM slot, and the jumper block is removed. Removing this block disables the logic board ROM and enables the ROM SIMM.

## Programmer's Switches

The programmer's switches (Reset and NMI) is located in the front of the Macintosh IIfx. This allows the IIfx to be placed on its side without restrictions regarding user access to the switch. This also makes it easier to move the computer off of the desk to a more convenient location. As long as the user has access to the front of the computer, which is necessary to gain access to the drive port and to view the power-on and HD-activity lamps, the user can reach the programmer's switches.

## Internal Hard Disk

As with the Macintosh IIfx, the Macintosh IIfx supports an internal hard disk drive. Since the IIfx has less internal space than the II and IIfx, the IIfx only supports 3.5-inch mechanisms.

Macintosh IIci: Specifications (Discontinued 2/93)

Article Created: 18 September 1989  
Article Reviewed/Updated: 8 July 1992

TOPIC -----

Following are the technical specifications for the Macintosh IIci.

DISCUSSION -----

### CENTRAL PROCESSING UNIT (CPU)

- Microprocessor : 25 MHz MC68030 CPU
- Address Bus : 32-bit
- Registers (32-bit) : 16 general-purpose data and address, two 32-bit Supervisor stack pointers, ten special-purpose control registers
- Addressing Modes : 18
- 256-byte instruction cache and 256-byte data cache
- Built-in Paged Memory Management Unit (PMMU)

### COPROCESSOR

- MC68882 floating-point unit (follows IEEE standards)

### MEMORY

- 1, 2, 4, 5, 8 MB RAM (Random Access Memory)  
80 nanosecond, Fast Page Mode DRAM
- RAM Parity error detection (Optional, Special Order)
- 512Kbytes of ROM (Read-Only Memory)
- 256 bytes of settable parameter memory with built-in battery backup

### KEYBOARD (not included)

- Apple Keyboard or Apple Extended Keyboard can be connected through the Apple Desktop Bus port

### MOUSE

- Apple Desktop Bus Mouse (ADB) mechanical tracking, optical shaft or contact encoding 100 +/- 10 pulses per inch

(3.94 +- 0.39 pulse per mm) of travel.

#### DISK DRIVE

- One 1.4 MB high-density internal Apple SuperDrive (formerly Apple FDHD). Only one internal, floppy drive is supported. The unit ships with the Apple SuperDrive, but the logic board also supports an 800K drive.
- External connector for 800K or 1.4MB external floppy

#### HARD DISK DRIVE

- 3.5" 40MB or 80MB hard drive configurations are available.

#### INTERFACES

- Two Apple Desktop Bus (ADB) connectors for keyboard, mouse, and low-speed input devices.
- Three NuBus Slots supporting full 32-bit address and data lines through a 96-pin Euro-DIN connector.
- Cache Connector supporting an optional high-speed RAM cache card. The connector is a 120-pin Euro-DIN connector.  
(\* NOTE: This connector IS NOT compatible with 030 Direct cards \*)  
(\* for the SE/30. Installing one of these cards in this slot can \*)  
(\* result in damage to the card and/or the logic board. \*)  
(\* As of September 1, 1991 the Apple Macintosh IIci Cache Card \*)  
(\* is included with all Macintosh IIci computers. \*)
- Two RS-232/RS-422 serial ports, 230.4K baud maximum (up to 0.920 Mbit per second if clocked externally).
- Built-In Video DB-15 pin connector, supporting the following monitors:
  - + Apple High-Resolution Monochrome Monitor at 2, 4, 16 and 256 grays
  - + AppleColor High-Resolution RGB Monitor at 2, 4, 16 and 256 colors/grays
  - + Apple Macintosh Portrait Display at 2, 4 and 16 grays
- SCSI interface
- Stereo sound port for external audio amplifier

#### SOUND GENERATION

- Apple Sound Chip (ASC) including 4-voice wave-table synthesis and stereo sampling generator capable of driving stereo mini-phono jack headphones or stereo equipment
- Mixed stereo monophonic sound output through internal speaker

#### ELECTRICAL REQUIRMENTS

- Line voltage: 100 to 240 volts AC, RMS automatically configured
- Line frequency: 50 to 60 hertz single phase
- Maximum power consumption: 130 watts maximum, 90 watts maximum continuous

#### ENVIRONMENTAL REQUIREMENTS

- Operating temperature: 50 TO 104 degrees F (10 TO 40 C)
- Storage temperature: -40 TO 116.6 degrees F
- Relative humidity: 5% to 95% (non-condensing)
- Altitude: 0 to 10,000 ft (0 to 3048 m)
- Fan: 17 CFM radial

#### SAFETY AND EMI QUALIFICATIONS

- FCC part 15 Class B Computing Devices
- UL 478 Electronic Data Processing Equipment

- CSA (Canadian Standards Assn.) 220 Information Processing and Business Equipment

SIZE AND WEIGHT

- Main Unit
  - Height: 5.5 inches (140 mm)
  - Width: 11.9 inches (302 mm)
  - Depth: 14.4 inches (365 mm)
  - Weight: 13 lbs. 10 oz. (6.2 kg)
- Apple Keyboard (not included)
  - Height: 1.8 inches (44.5 mm)
  - Width: 16.5 inches (418.3 mm)
  - Depth: 5.6 inches (142.0 mm)
  - Weight: 2 lbs. 2 oz. (1 kg)
- Apple Extended Keyboard (not included)
  - Height: 2.3 inches (56.4 mm)
  - Width: 19.1 inches (486 mm)
  - Depth: 7.4 inches (188 mm)
  - Weight: 3 lbs. 10 oz. (1.6 kg)
- Apple Mouse (ADB)
  - Height: 1.1 inches (27.9 mm)
  - Width: 2.1 inches (53.3 mm)
  - Depth: 3.8 inches (96.5 mm)
  - Weight: 6 oz. (.175 kg)

## Apple Data Modem Int'l XP 2400 Modem: Specs (Discontinued)

Revised: 9/13/93  
Security: Everyone

Apple Data Modem Int'l XP 2400 Modem: Specs (Discontinued)

=====

Article Created: 18 Spetmebr 1989

### I. Technical Specifications

#### A. Regulatory

1. Refer to the modem for specific European registration information.

#### B. Data Format

1. Protocol: Asynchronous
2. Character Length
  - a. 7 data bits
    - 1) Stop bits: 1 or 2
    - 2) Parity: Odd, even, fixed: mark/space
  - b. 7 data bits
    - 1) Stop bits: 2
    - 2) No parity
  - c. 8 data bits
    - 1) Stop bits: 1 or 2
    - 2) No parity
3. Mode: Full duplex

#### C. Compatibility

1. Subset of Hayes AT modem command set

#### D. Error Correction (optional)

1. Microcom Network Protocol (MNP) Classes 4 through 5  
Added via daughterboard to modem card

#### E. Transmission Speeds

1. For all speeds
  - a. Tolerance in character asynchronous format (DTE data rate)
    - 1) +1.0%
    - 2) -2.5%
  - b. Tolerance in modulation rate
    - 1) +/- 0.01%

2. 2400 bits per second (bps)
  - a. Standard: V.22bis
  - b. Modulation: Quadrature Amplitude Modulation (QAM)
3. 1200/75 bits per second (bps)
  - a. Standard: V.23
  - b. Modulation: Frequency shift keying (FSK)
4. 1200 bits per second (bps)
  - a. Standard: V.22A/B, Bell 212A
  - b. Modulation: Differential phase-shift keying (DPSK)
5. 300 bits per second (bps)
  - a. Standard: Bell 103
  - b. Modulation: Frequency shift keying (FSK)

F. Operating Modes

1. Auto or manual dial (including redial)
  - a. Tone: DTMF (Dual-Tone Multi-Frequency--"Touch Tone")
    - 1) Frequency tolerance: +/- 1/0%
    - 2) Tone balance: Within 3dB
  - b. Pulse (Rotary)
    - 1) Dialing duty cycle: see specific modem for mark/break ratio
    - 2) Dialing rate: 10 pps
2. Auto or manual answer

G. Receiver Dynamic Range

1. -10 to -43 dBm, full duplex

H. Transmitter Level

1. Refer to the modem for specific registration information.

I. Command Buffer

1. 40 characters

J. Computer interface

1. 18-pin dual-in-line female connector

K. Power Requirement

1. DC input
  - a. +5.2V +/- 5%
  - b. -5.0V +/- 5%

L. Power Consumption

1. 800 mW maximum

II. System Configuration

A. Computer

1. Macintosh Portable

B. Modem Configuration

1. Universal internal modem card
2. External country specific Data Access Arrangement (DAA) module.

It plugs into the internal card via an attached Mini-DIN 8 cable.

C. Country specific phone cable appropriate for DAA

## Apple Extended Keyboard II - ISO Layout: Specifications

Revised: 8/5/92  
Security: Everyone

Apple Extended Keyboard II - ISO Layout: Specifications

=====

This article last reviewed: 4 December 1989

### --Description:

The "Apple Extended Keyboard II - ISO layout" is a keyboard specially designed for the European market. The layout complies with ISO 1091 standard on the "Layout of printing and function keys."

### --Packing List (M0312Z):

Apple Extended Keyboard II - ISO layout  
1.0 m (3 ft.) ADB cable  
Double-sided template to place over function keys  
Owner's guide  
Warranty statement

### --System Requirements:

Any Apple personal computer with an Apple Desktop bus interface  
International Macintosh System Software: Version 6.0.3 or later  
US Macintosh System Software: Version 6.0.4 or later

### --Technical Specifications:

Total 106 keys, including  
18-key numeric pad  
15 function keys  
4 arrow cursor-control keys in inverted T-style layout  
6 cursor-control keys (Home, Page Up, Page Down, Forward Delete, End, and Help)

### --Size and Weight:

Front Height: 19 mm (0.75 in.)  
Rear Height: 41 mm (1.6 in.)

|                 |                   |
|-----------------|-------------------|
| Keyboard angle: | 14 degree maximum |
|                 | 6 degree minimum  |
| Width:          | 475 mm (18.7 in.) |
| Depth:          | 195 mm (7.7 in.)  |
| Weight:         | 1.8 kg (4.8 lbs)  |

--Product Details:

The keyboard has 15 function keys (F1-F15) and 6 cursor-control keys (home, Page Up, Page Down, Forward Delete, End, and Help).

F1-F4 are labeled on the housing under the keys F1=undo, F2=cut, F3=copy, and F4=paste. These are not predefined default values; however, developers are being encouraged to use these definitions as appropriate. The remaining 11 function keys can also be defined by the user. A template is provide for users to mark the key's function.

The function keys are operative by using a macro utility program or by using an MS-DOS application with the appropriate coprocessor card.

The Caps Lock LED is operative in the Macintosh environment. The Num Lock and Scroll Lock are not operative except by using an MS-DOS application with appropriate coprocessor card. Developers are being encouraged to support these LED's in their applications.

The keyboard has an adjustable foot in the rear of the keyboard. The height of the keyboard is adjusted with a lever in the rear of the keyboard. It can be adjusted with a tilt from the unextended 6 degree to a maximum of 14 degrees from horizontal.

## Macintosh Portable: Internal Modem Installation Guide

Revised: 9/18/89  
Security: Everyone

Macintosh Portable: Internal Modem Installation Guide

=====

This article last reviewed: 18 September 1989

All power must be disconnected before the modem can be installed. The AC adapter must be disconnected, the main battery removed and the battery cover must be in place to shut off the backup battery to insure the unswitched +5 volt connection is disconnected. If the power is not completely shut off, the modem may be damaged.

Note: This action will cause all RAM to lose power. This will erase RAM disks, reset all Control Panel settings including the system clock and lose any unsaved documents which are open.

This procedure is also the recommended method to hardware reset the modem.

## Macintosh Portable Data Modem 2400: Specifications(Discontinued)

Revised: 6/21/94  
Security: Everyone

Macintosh Portable Data Modem 2400: Specifications(Discontinued)

=====

Article Created: 2 October 1989  
Article Reviewed/Updated: 16 March 1994

TOPIC -----

This articles gives the technical specifications for the Macintosh Portable Data Modem 2400.

DISCUSSION -----

### I. Technical Specifications

#### A. Regulatory

1. FCC Registration Number: BCGM0250
2. Ringer Equivalence Number: 0.3B
  - a. The total number of ringer equivalence numbers on any one telephone line cannot exceed 5.0.
3. Canadian Load Number: 9

#### B. Data Format

1. Protocol: Asynchronous
2. Character Length
  - a. 7 data bits
    - 1) Stop bit: 1
    - 2) Parity: Odd, even, fixed: mark/space
  - b. 7 data bits
    - 1) Stop bits: 2
    - 2) No parity
  - c. 8 data bits
    - 1) Stop bits: 1
    - 2) No parity
3. Mode: Full duplex

#### C. Compatibility

1. Subset of Hayes AT modem command set

D. Transmission Speeds

1. For all speeds
  - a. Tolerance in character asynchronous format (DTE data rate)
    - 1) +1.0%
    - 2) -2.5%
  - b. Tolerance in modulation rate
    - 1) +/- 0.01%
2. 2400 bits per second (bps)
  - a. Standard: V.22bis
  - b. Modulation: Quadrature Amplitude Modulation (QAM)
3. 1200 bits per second (bps)
  - a. Standard: V.22, Bell 212A
  - b. Modulation: Differential phase-shift keying (DPSK)
4. 300 bits per second (bps)
  - a. Standard: Bell 103
  - b. Modulation: Differential phase-shift keying (DPSK)

E. Operating Modes

1. Auto dial (including redial)
  - a. Tone: DTMF (Dual-Tone Multi-Frequency--"Touch Tone")
    - 1) Frequency tolerance: +/- 1/0%
    - 2) Tone balance: Within 3dB
  - b. Pulse (Rotary)
    - 1) Dialing duty cycle: 39%/61% or 33%/67% mark/break ratio
    - 2) Dialing rate: 10 pps
2. Auto or manual answer

F. Receiver Dynamic Range

1. -10 to -43 dBm, full duplex

G. Transmitter Level

1. -10dBm +/- 1dB, fixed as per FCC interconnect specification, Part 68

H. Command Buffer

1. 40 characters

I. Computer interface

1. 18-pin dual-in-line female connector

J. Power Requirement

1. DC input (U.S. and Canada)
  - a. +5.2V +/- 5%
  - b. -5.0V +/- 5%

K. Power Consumption

1. Operational mode:
  - a. 750 mW maximum
  - b. 525 mW typical
2. Sleep Mode
  - a. 3 mW maximum

II. System Configuration

A. Computer

1. Macintosh Portable

B. Standard single-line telephone cable with RJ-11 modular jack

## Macintosh Portable: Battery

Revised: 7/30/92  
Security: Everyone

Macintosh Portable: Battery

=====

Article Created: 13 September 1989  
Article Last Reviewed: 30 July 1992  
Article Last Updated:

TOPIC -----

This article describes the Macintosh Portable sealed, lead-acid battery.

DISCUSSION -----

The Macintosh Portable uses a sealed, lead-acid (SLA) battery. SLA cells have a constant voltage drop as they lose their charge. This enables the Macintosh Portable to alert the user when power is running low.

The cycle life of an SLA battery varies depending on the depth of discharge. If the battery is discharged to 100% of the energy in the battery, the battery can get 200 charge/discharge cycles before it has to be replaced. If discharged to 25% depth, the battery can get 2,000 charge/discharge cycles. The recharging system used in the Macintosh Portable keeps the battery at full charge to extend the number of charge/discharge cycles.

The external battery recharger charges a spare battery when the user is still using the Macintosh Portable. It uses the same power adapter as the Macintosh Portable, and has the same power input requirements as the Macintosh Portable power adapter (120/240 VAC 50/60Hz). It includes a recharge cradle to hold the battery. The battery charger LED, located on the top of the unit, will display:

| LED Color      | Status          |
|----------------|-----------------|
| -----          | -----           |
| Amber (Yellow) | Charging        |
| Green          | Fully Charged   |
| No Light       | Replace Battery |

## Macintosh: Liquid Crystal Displays (LCDs) Compared (3/95)

Revised: 3/23/95  
Security: Everyone

Macintosh: Liquid Crystal Displays (LCDs) Compared (3/95)

Article Created: 13 September 1989  
Article Reviewed/Updated: 23 March 1995

TOPIC -----

This article gives an overview of active- and passive-matrix liquid crystal displays.

DISCUSSION -----

Liquid Crystal Display (LCD) is the display technology used on the screens of Macintosh Portable and PowerBook computers. LCDs are non-emissive (no Extra Low Frequency (ELF) or Very Low Frequency (VLF) emissions); they do not create their own light, but reflect and block light. (The PowerBook series includes a bulb to aid in viewing the screen at different light levels.) LCDs use a reflector, backlight, sidelight, or a combination of a reflector and back/sidelight to send the image to the user. The main difference from a Cathode Ray Tube (CRT) display is that the pixel (the little dots of light that comprise the picture on a computer or TV screen) is not the source of light. A typical LCD consists of a reflector, rear polarizer, back glass, liquid crystal material, front glass, and front polarizer.

The liquid crystal material is a liquid with rod-shaped molecules inside. The rod-shaped molecules can form a twisting helix, or spiral pattern and bend light that enters the display. When a current is applied, the rods straighten out and no longer bend the light. The inside surfaces of the glass are treated and polished to induce the rod-shaped molecules in the liquid crystal material to line up with the polarizers.

The display uses two polarizers to line up the light and reduce glare. If the light is out of phase, it can not pass through the polarizer. By using two polarizers 90 degrees out of phase with each other, the light is blocked. The liquid crystal material bends the light 90 degrees so it will pass through the polarizer. When the LCD has power to it, it does not bend the light, hence it does not pass through the polarizer.

This type of display is called an active matrix, or Thin-Film Transistor (TFT), display. Passive matrix, or Film SuperTwisted Nematic (FSTN), displays are similar to TFT displays, but the liquid crystal molecules in a SuperTwist Display bends or twists light much farther than in a standard TFT display. In fact, the molecules in a SuperTwist display can bend 270 degrees or more to transmit light. One difference you may notice between passive and active matrix screens is that active matrix has a much wider viewing range than passive matrix. In other words, you can see information displayed on the screen from a wider side angle on an active matrix display than on a passive matrix display.

#### Passive Matrix

-----

In a passive matrix, or Film SuperTwisted Nematic (FSTN), display a grid of electronic control wires or lines are placed on the front and back glass. A pixel is located at the junction of each row and column control lines. Passive matrix displays use one transistor to address each row and one to address each column of pixels. Pixels are turned on when both row and column lines are energized and off when both control lines are de-energized. This addressing scheme is called multiplexing.

The residual electrical current that travels down each control line can cause crosstalk at unselected pixels. Crosstalk partially darkens pixels and lowers the display's overall contrast. This usually appears on a passive matrix PowerBook display as two dark boxes, parallel to each other on the display.

#### Active Matrix

-----

The active matrix, or Thin-Film Transistor (TFT) display is the latest technology used in Macintosh PowerBook computers. Rather than using multiplexing (row and column wires on the glass) techniques to address the matrix of crystals, the active matrix LCD includes a transistor fabricated along with each pixel. You can think of the display as one large Integrated Circuit (IC), with the transistors acting as switches to turn on individual pixels. (An IC is a slice or chip of material on which is etched or imprinted a circuit comprised of electronic components and their interconnections.) Because of the transistors, pixels can be turned on and off at a very fast rate. The transistor at each pixel eliminates the crosstalk phenomenon, which lowers contrast on an FSTN display.

The TFT method eliminates the time dependency associated with multiplexed displays by directly addressing each pixel.

## Macintosh Portable: Internal 40SC Hard Disk

Revised: 7/27/92  
Security: Everyone

Macintosh Portable: Internal 40SC Hard Disk

Article Created: 13 September 1989  
Article Last Reviewed: 27 July 1992  
Article Last Updated:

### TOPIC -----

This article gives the a technical description of the Macintosh Portable Internal 40SC Hard Disk.

### DISCUSSION -----

The Macintosh Portable Internal 40SC Hard Disk provides fast, reliable access to high-performance storage and large-capacity applications. One-inch high, weighing 1.1 pounds, the Macintosh Internal Hard Disk 40SC has been designed especially for use with the Macintosh Portable. It draws little power from system batteries and virtually eliminates disk swapping, because it can accomodate multiple applications, complex documents, and large databases in one convenient location.

### SPECIFICATIONS

Mechanism Size : 3.5 Inches

#### CAPACITY 40MB

- Data Capacity: 40MB Formatted
- Data surfaces: 2
- Heads/Surfaces: 1
- Block Size: 512 bytes
- Total disk blocks: 82,080
- Blocks/Tracks: 40

#### CHARACTERISTICS

- Average Seek Time : 25 milliseconds
- Rotational Speed: 3,557 rpm
- Startup Time: 20 seconds

# ..TIL04485-Macintosh\_Portable-Internal\_40SC\_Hard\_Disk\_(TA40409).pdf

- Spin-down Time: 10 seconds
- Automatically retracks to the inner stop (non-data area) upon power down to protect data area during travel and startup.

## ENVIRONMENTAL

- Operating Temperature: 50 degrees F to 104 degrees F (10 degrees C to 40 degreesC)
- Non-Operating Temperature: 32 degrees F to 122 degrees F (0 degrees C to 50 degrees C)
- Humidity: 20% to 80% relative humidity non condensing

Interface : internal 34-pin connector

## Macintosh Portable: Power-Saving Features

Revised: 7/30/92  
Security: Everyone

Macintosh Portable: Power-Saving Features

=====

Article Created: 13 September 1989  
Article Last Reviewed: 30 July 1992  
Article Last Updated:

TOPIC -----

This article describes Macintosh Portable computer's power saving features.

DISCUSSION -----

The Macintosh Portable has a number of power-saving features that give it 6 to 12 hours of battery life. The Macintosh Portable contains two batteries: a main battery that provides power while the computer is in use, and a backup 9-volt transistor battery that sustains the computer's memory while the main battery is disconnected (as when a fresh main battery is being installed).

Note: The main battery is required for operation of the Macintosh Portable. The hard drive will not spin up without the internal battery.

The power-saving features are controlled by the power-manager processor. The power-manager processor is a separate "computer" inside the unit that controls the power functions of the unit.

The Macintosh Portable is the only member of the Macintosh family that is designed to be powered by a battery. In normal operation, the Macintosh Portable never switches off. Rather, it goes into a low-power consumption\ state, the sleep state, when it is not in use. Ideally, the Macintosh portable is switched on only when the battery is first installed or after the battery has been removed to install an expansion card in the machine.

Sleep

-----

System sleep helps the Macintosh Portable operate longer between charges.

## ..TIL04486-Macintosh\_Portable-Power-Saving\_Features\_(TA40410).pdf

When in sleep state, the Macintosh Portable maintains full power to system RAM, video RAM, and the power-manager processor. The power-manager processor stops the clocks to the SCC, the SWIM, and the ASC. Stopping the clocks to these devices, reduces their power consumption to almost zero without requiring that they be reset. The power-manager processor switches off power to the serial drivers, ROM, flat panel display, the ASC, the Sony sound chips, the SCSI, and to a variety of pull-up resistors and other components. The power-manager processor also sends a signal to the internal modem that causes the modem to shut itself down, if not in use.

The system can enter sleep in the following ways:

- The user selects sleep from the Special menu in the Finder.
- The user selects sleep from the Battery DA.
- The system enters sleep after a period of inactivity (the interval is user selectable).
- The system enters sleep, because battery power is at the software-shutdown level.
- This is the first time power is being applied.
- The power-manager processor is reset.

The system will not enter sleep, if the internal modem is executing an AT command or if the modem is off-hook, except at hardware shutdown.

Macintosh Portable will come out of sleep for any of the following reasons:

- A key is pressed on the keyboard (except Caps Lock).
- The wake-up timer matches the real-time clock.
- The internal modem is installed, and a ring detect comes in, while the modem is set to watch for ring detect.

Note: If the unit is in software shutdown, the Macintosh Portable does not come out of shutdown until the power adapter is plugged in or until the battery is replaced.

When power is first applied to the Macintosh Portable, the power-manager processor immediately puts the system into the sleep state. When a key is pressed, the power-manager processor initiates a system reset and the Macintosh Portable goes through the same sequence of start-up events as the Macintosh SE.

Macintosh Portable presents four dialogs to the user when the battery is running low. The first three warn the user about the power condition, and the last lets the user know the system is going to sleep mode.

## Sleep vs Shut Down

-----

The Shut Down menu item doesn't care about memory contents and quits applications before shut down. Sleep saves memory contents. Shut Down should be used for the following:

- To have the unit wake up and reboot
- To add an external peripheral
- To make sure all applications have been quit
- Hard Drive Sleep. If the Macintosh Portable has a hard drive, the control panel displays an option to put the hard drive to sleep. This causes the hard drive to stop spinning. Hard drive sleep automatically occurs when the Macintosh Portable goes into system sleep.

Any hard disk activity causes the Macintosh Portable to come back out of hard drive sleep. It takes one or two seconds for the hard drive to get up to speed, slowing access to the drive.

## Rest

----

The power-manager processor monitors the amount of time the Macintosh Portable has been inactive. After a period of 15 seconds without any activity, the unit goes into Rest mode. It causes the CPU to insert 64 wait states into RAM and ROM accesses which lowers the effective clock rate to approximately 1 MHz. Interrupts continue to be processed at the same rate. As soon as the trackball or mouse moves, or any peripheral device is activated, the computer comes up to full speed instantly.

The following items are checked and stop the unit from entering rest mode:

- Mouse movement
- I/O activity, (keyboard, trackball, modem, etc..)
- Cursor change
- Serial port access

This feature can be turned off, when running Video Works or some other program that avoids detection by the rest routine. The user can disable rest mode by doing the following:

- 1) Enter the Control Panel DA and select the Portable icon.
- 2) Hold Down the Option key and click the words "Minutes Until Automatic Sleep."
- 3) Click on Don't Rest in the dialog box that comes up, and select OK

## Low Power Warnings

-----

When the battery starts to run low, a series of messages appears, warning the user that it is time to recharge. A flashing battery replaces the Apple Icon in the menu bar. When these messages start to appear, save any open documents and plug the Macintosh Portable into the power adapter as soon as possible. (Saving work is a good thing to do every once and a while, anyway.) The computer can be active, while it is recharging the battery.

After the fourth warning, the computer automatically goes into system sleep, while there is still enough power to hold the contents of memory for five days.

Note: As long the battery is recharged within five days, the contents of memory remain intact, and the computer will pick up where it left off before the battery ran low. The only consequence of not recharging within five days is that the contents of memory are lost.

When not using the computer for more than one month, save any files and select Shut Down from the Special menu. After shut down, remove the battery to make sure the battery does not become completely discharged.

## Macintosh Portable: Specifications (Discontinued)

Revised: 10/18/95  
Security: Everyone

Macintosh Portable: Specifications (Discontinued)

Article Created: 13 September 1989  
Article Reviewed/Updated: 18 October 1995

TOPIC -----

This article gives specifications for the Apple Macintosh Portable computer.

DISCUSSION -----

The Apple Macintosh Portable computer offers complete Macintosh functionality in a portable design. It runs virtually all current versions of Macintosh software and provides full compatibility with other Macintosh hardware. There are two versions of the Macintosh Portable. The new Macintosh Portable features a backlight for added display visibility in low-light conditions.

The Apple Macintosh Portable computer is the one Macintosh for the workplace, home, and any destination. With built-in networking and the ability to run virtually all current versions of Macintosh software twice as fast as the Macintosh Classic, the Macintosh Portable gives you all the capabilities you need for your primary computer.

You also can take the Macintosh Portable with you and use it at meetings, at a client's office, or at home because everything you need--central processing unit (CPU), screen, standard size keyboard, pointing device, battery, and disk storage--is integrated into a single, easy-to-carry package.

The Macintosh Portable delivers the superior graphics that people have come to associate with the Macintosh. Its backlight, active-matrix liquid crystal display (LCD) lets you see the full page width for easy editing of word-processing and other documents. This screen also has such a fast response time that the Macintosh interface looks and feels just like any other Macintosh computer. And the display's backlighting can be adjusted for a wide range of lighting situations, so you can see the screen as

easily in bright light as you can in a dimly lit room.

The Macintosh Portable has been designed to conserve power and extend battery life, so you can use it for 3 to 6 hours (6 to 12 on non-backlighted units) before the battery needs recharging. A battery desk accessory monitors and warns you when the battery is getting low.

Like other Macintosh computers, the Macintosh Portable comes with the 1.4 MB SuperDrive, which allows you to work easily in different computing environments because it can read from and write to 3.5-inch Macintosh disks as well as MS-DOS, OS/2, and ProDOS disks. In addition, an internal 40MB hard disk drive accommodates large files and applications. You'll also find plenty of opportunities to extend the Macintosh Portable's capabilities. You can use eight built-in ports to expand the system with popular peripheral equipment, such as scanners and printers.

Four internal expansion slots let you customize the Macintosh Portable to your specific needs. Your system can accommodate up to 8 MB of memory if you use third-party memory cards in the processor-direct slot. You also can use the processor-direct slot to add high-performance expansion cards for video, networking, and communications.

#### Specifications:

##### CENTRAL PROCESSING UNIT (CPU)

- Microprocessor: 16MHz CMOS 68000
- Address Bus: 24-bit
- Registers (32-bit): 17
- Addressing Modes: 14

##### COPROCESSOR

- Power Manager Processor, Mitsubishi M50753 microcomputer chip

##### MEMORY

- Original Macintosh Portable: 1 MB of static RAM, expandable to 2 MB through the installation of a memory card in the RAM slot, and up to 9 MB when higher-density chips become available; 1 Wait state to access SRAM
- New Macintosh Portable: 1, 2, or 4 MB of pseudostatic RAM, 2 and 4 MB through the installation of a memory card in the RAM slot, and up to 8 MB through the PDS slot (Apple Memory Card must be removed when you install a PDS memory card)\*; 0 wait states to access PSRAM; PSRAM has a refresh cycle to refresh the chips every 15.6  $\mu$ seconds.
- 256K bytes of ROM (Read-Only Memory)
- 128 bytes of settable parameter memory with built-in battery backup
- 32K bytes of RAM for the video display

##### SCREEN

- Active-Matrix Liquid Crystal
- Full-page width
- 640x400 pixels
- New Macintosh Portable features a CCFL backlight for up to 55 nits of brightness

#### KEYBOARD

- Built-in 63-key keyboard
- Optional 18-key numeric keypad (as trackball alternative)
- Keyboard on New Macintosh Portable uses quiet keyswitches

#### TRACKBALL

- Low-power Apple Desktop Bus Trackball, 1.3-inch diameter trackball as pointing device
- Left- or right-hand placement
- Replaceable by numeric keypad

#### MOUSE

- Low-power Apple Desktop Bus Mouse (ADB), mechanical tracking, optical shaft encoding at 3.54 pulses per mm (90 pulses per inch) of travel

#### DISK DRIVE

- One 1.4 MB high-density SuperDrive (internal); two internal floppy drives when hard drive is not installed
- External connector for 800K or 1.4 MB external floppy

#### HARD DISK DRIVE

- A low-power, ruggedized internal 3.5-inch 40MB drive
- 40MB hard drive is standard on the new Macintosh Portable

#### INTERFACES

- One Apple Desktop Bus (ADB) connector for keyboard, mouse, and low-speed input devices
- Two RS-232/RS-422 serial ports, 230.4K baud maximum (up to 0.920 Mbit per second if clocked externally)
- SCSI interface
- Stereo sound port for external audio amplifier
- External drive port
- External video port

#### SOUND GENERATION

- Apple Sound Chip (ASC) including 4-voice, wave-table synthesis and stereo sampling generator capable of driving stereo mini-phono-jack headphones or stereo equipment
- Mixed stereo monophonic sound output through internal speaker

#### ELECTRICAL REQUIRMENTS

- Line voltage: 70 to 270Vac
- Line frequency: 48 to 62Hz
- Maximum power consumption: 15 watts

#### ENVIRONMENTAL REQUIREMENTS

- Operating temperature: 50 to 104F (10 to 40C) degrees
- Storage temperature: -40 to 140F (-25 to 60C) for a period not to exceed 3 days; storage for longer periods must be within operating temperature range
- Relative humidity: 5% to 95%
- Altitude: 0 to 10,000 feet (0 to 3048m)

#### SIZE AND WEIGHT

- Height
  - Rear panel: 4.05 inches (102.87mm)
  - Front panel: 2.1 inches (53.34mm)
  - Base to highest point with display open: 11.0 inches (279.4mm)
- Width: 15.25 inches (387.35mm)
- Depth: 14.83 inches (365.25mm)
- Weight (including battery): 13.75 lbs. (6.25kg)
- Weight (including battery and hard drive): 15.75 lbs. (7.16kg)

-----

Here is a list of changes to the Macintosh Portable.

#### Original Macintosh Portable

-----

- 640x400 Active-Matrix Display
- 1MB SRAM on logic board, 1 wait state
- Screen brightness-controlled contrast
- 1MB Memory Card
- System Software 6.0.4
- Backlight upgrade available
- Standard keyswitches
- Hybrid chip
- Custom Macintosh Portable manuals
- Steel plate in keyboard
- 6- to 12-hour battery life
- Apple Memory Card and third-party PDS card memory supported

#### Backlight Macintosh Portable Model

-----

- 640x400 Backlight Active-Matrix Display
- 1MB CMOS Pseudostatic RAM, 0 wait states
- CDEV controls backlight
- 1MB and 3MB Memory Cards Pseudostatic
- System Software 6.0.7 and new CDEV disk
- Backlight standard
- Quiet keyswitches
- Custom resistor packs
- Standard manual suite with Macintosh Portable handbook
- Aluminum plate for keyboard
- 3- to 6-hour battery life
- Third-party PDS card memory cannot be used when Apple Memory Card is installed\*

\*A problem with the memory decode chip on the Apple Memory Cards (1 MB and 3 MB) prevents third-party memory cards in the PDS slot from correctly addressing memory.

## Macintosh Portable: External Video Port Pinouts

Revised: 7/27/92  
Security: Everyone

Macintosh Portable: External Video Port Pinouts

Article Created: 13 September 1989  
Article Last Reviewed: 27 July 1992  
Article Last Updated:

TOPIC -----

This article describes the external video port pinouts of the Macintosh Portable.

DISCUSSION -----

The External Video Port drives video devices with a digital signal. It does not provide an analog signal used by a monitor.

Display Electronics

The display uses a digital signal to generate information, not an analog signal like a CRT. There are three signals generated in the video logic IC:

- the pixel synchronization signal; it marks the end of a byte.
- the horizontal synchronization signal; it marks the end of a 640 pixel line.
- the vertical synchronization signal; it marks the beginning of a new video frame.

The Macintosh Portable produces signals for an external video display through an 8-bit interface that is similar to the interface for the built-in display. A video adapter is required to convert the 8-bit data stream into a signal that can drive an external video device.

Connector: Density and 1/2 15-pin (same size as DB-9 with 15 pins)

PINOUTS

- 1 - FPDATA(0) Data bit 0
- 2 - FPDATA(1) Data bit 1
- 3 - +5 volts \*\*
- 4 - FPDATA(2) Data bit 2
- 5 - FPDATA(3) Data bit 3
- 6 - FPDATA(4) Data bit 4
- 7 - GND Signal Ground
- 8 - +5 volts \*\*
- 9 - GND Signal Ground
- 10 - FPDATA(5) Data bit 5
- 11 - FPDATA(6) Data bit 6
- 12 - FPDATA(7) Data bit 7
- 13 - BATT\_VOLTAGE
- 14 - FLM from Video chip, Begin frame scan over
- 15 - CL2/ from Video chip, Byte clock

\*\* Maximum current on 5 volt line is 50ma

## AppleShare PC 2.0: How To Configure for DOS 4.0

Revised: 10/4/89  
Security: Everyone

AppleShare PC 2.0: How To Configure for DOS 4.0

=====

This article last reviewed: 12 September 1989

TOPIC -----

I have installed a 3COM EtherLink/MC card into a PS/2 Model 50z running DOS 4.0.

I also installed AppleShare PC 2.0 with EtherLink/MC options (with standard setting on the interrupt level, DMA, and and so on). I have no other interface cards except a 1MB RAM upgrade in the machine.

However, when I restart the machine, it hangs at:

"Initializing AppleTalk. One moment please..."

Is AppleShare PC 2.0 incompatible with DOS 4.0, or did I do something wrong?

DISCUSSION -----

AppleShare PC 2.0 is compatible with DOS 4.0, but it appears that you missed one item.

You need to select "3" as the primary interrupt line for the MLID used by this card (ETHER\$). If you leave the default interrupt line intact, it will certainly fail.

Both the default primary memory address 0C0000H and the default primary port address 0300H are correct and do not need to be changed.

Security: Everyone

HyperCard: AppleTalk XCMDs to Query Networks

=====

Article Created: 12 September 1989  
Article Last Reviewed: 10 August 1992  
Article Last Updated:

TOPIC -----

I have over 200 zones on my AppleTalk network; it has become far too much trouble to look for devices through the Chooser. Can I use AppleTalk HyperCard XCMDs to build an intelligent stack to query the network for devices and inform the user?

DISCUSSION -----

The AppleTalk XCMDs can do this. There is, however, one feature missing that would require some extra work. Because the XCMDs do not provide zone information, you need to know the zone names prior to looking up the devices.

The only constraints on creating a stack to do AppleTalk device queries are machine configurations. For this stack to be a workable solution, you should be running MultiFinder or System 7, and you should use a hard disk.

## A/UX: How To Convert PICT File to PostScript (9/94)

Revised: 9/9/94  
Security: Everyone

A/UX: How To Convert PICT File to PostScript (9/94)

=====

Article Created: 12 September 1989  
Article Reviewed/Updated: 8 September 1994

TOPIC -----

Under A/UX, can I take a PICT format file and convert it to a PostScript file without going through a printer? It seems that all the toolbox calls to do such a thing are only in the Print Manager.

DISCUSSION -----

The simplest way to convert a PICT file may be to use Command-F from the print dialog of an application that can print PICT documents. (MacDraw is a good example.) You don't have to connect a LaserWriter for this to work.

Make sure the LaserWriter driver has been chosen from among the different options in the Chooser. Don't worry about not being able to actually select a LaserWriter.

When you get to the MacDraw print dialog, click the OK button, then immediately press and hold Command-F. You should see the message "Creating PostScript File" at the top of your screen above the normal MacDraw "print progress" indicator. You can release the keys when you see this message.

This puts a PostScript file in /usr/lib/Macintosh named PostScriptN, where N starts at 0 and increases by 1 each time you generate a PostScript file this way (up to a maximum of 9).

If this is not an acceptable solution, there are also Macintosh OS applications that can read PICT files and save them as PostScript. One of these which also runs under A/UX is Adobe Illustrator 88. Illustrator 88 can read a MacDraw II-generated PICT file and save it as PostScript.

## Abaton Scanner Upgrade: Incompatible with AppleScan

Revised: 1/18/93  
Security: Everyone

Abaton Scanner Upgrade: Incompatible with AppleScan

=====

Article Created: 4 October 1989

### Article Change History

-----

1/15/93 - UPDATED  
• Abaton is now Everex Systems.  
9/26/89 - REVIEWED  
• For accuracy.

### TOPIC -----

This article concerns the incompatibility of the Abaton 8-bit upgrade with Apple's scanning software.

### DISCUSSION -----

Abaton's (now Everex Systems) 8-bit upgrade for the Apple Scanner -- a logic board swap -- may create more problems than it solves. An upgraded scanner does not work with the AppleScan or HyperScan software.

If you only use gray scale images, Digital Darkroom or Image Studio are probably more appropriate pieces of software. The upgrade does not affect them.

However, for more general scanning (line art, halftone, and HyperCard images), the Apple software (AppleScan and HyperScan) is the usual choice. This software does NOT work with the upgrade.

## Apple Equipment: Special Enclosures for Dirty Environments

Revised: 6/8/92  
Security: Everyone

Apple Equipment: Special Enclosures for Dirty Environments

=====

Article Created: 4 October 1989  
Article Last Reviewed: 1 June 1992  
Article Last Updated:

TOPIC -----

Are there ways to ensure cleanliness for the Macintosh operating environment?

I need to install about 500 Macintosh IIcx systems in truck garages and loading docks. Are there any special covers or enclosures that filter fumes and soot, but still permit access to a Macintosh IIcx? Also, is there anything that prevents the typical mechanic from setting a wrench or dripping oil can on top of the equipment? Proper air circulation is my main concern.

Aso, is it necessary (or possible) to "ruggedize" an AppleCD SC for this environment? Mechanics aren't very gentle with the ROM caddies.

DISCUSSION -----

What you really need is a NEMA (National Electrical Manufacturers Association) enclosure. Check your local area for a NEMA office that can make recommendations.

The two big issues are heat and dirt. To keep the dirt (air-based carbons and oil from diesel trucks) out of the system requires filters that restrict the airflow. Reduced airflow equals increased heat, which reduces the system's life span. Without filters, the soot gets into the fan bearings, slowing it down and increasing heat.

Adapting the AppleCD SC to these conditions results in the same sorts of problems.

## Macintosh: Multiple SCSI Device Startup Problems

Revised: 10/4/89  
Security: Everyone

Macintosh: Multiple SCSI Device Startup Problems

=====

This article last reviewed: 13 September 1989

TOPIC -----

I have a Macintosh IIX with internal HD80 SC drive, AppleCD SC, and Apple Scanner. When all devices are connected, the last device on the SCSI chain does not show up.

I have already tried switching the order of devices, changing SCSI ID numbers, and starting up the three machines in every possible order. The last device is terminated but I still can't see it. The first device always works (whether it's the AppleCD SC or the Apple Scanner).

Do you have any suggestions?

DISCUSSION -----

You are encountering a problem known as impedance matching. This is a known problem with the Apple Scanner. The situation occurs when the impedance created by a combination of devices and terminators on the SCSI chain causes one device to be "lost" on the chain.

Change the impedance of the SCSI chain by adding one or more terminators, SCSI devices, and/or additional SCSI extender cable, and the device will reappear.

## Apple Scanner: How To Get Straight Lines

Revised: 10/4/89  
Security: Everyone

Apple Scanner: How To Get Straight Lines

=====

This article last reviewed: 13 September 1989

TOPIC -----

This article explains how to get horizontal and vertical lines straight when scanning. (This applies primarily to line art images.)

DISCUSSION -----

After previewing the image, use the selector tool to focus on an area that has a vertical or horizontal line. Select the Threshold setting and the Settings window appears. Click the Apply button and view the current alignment of the original image on the scanner bed.

If the scanned line is not straight, lift the scanner lid, rotate the original slightly, and click again on Apply. Repeat this until the horizontal or vertical line is straight. When the line is straight, put the lid down and scan the entire page.

The scanned lines now should be straight (assuming the original is straight).

## Macintosh-to-VME Connectivity Solution

Revised: 10/4/89  
Security: Everyone

Macintosh-to-VME Connectivity Solution

=====

This article last reviewed: 13 September 1989

TOPIC -----

Here is one solution for Macintosh-to-VME connectivity.

DISCUSSION -----

A company in Holland advertises a direct connection from the Macintosh II family to a VME bus.

The company, Bergoz, makes an interface called MacVEE, which consists of a NuBus card with DMA and a connection through a flat cable to a VME and CAMAC subrack. The cable can be up to 100 meters. (The MacVEE product was developed at the European CERN, a large research institute based in Geneva.)

For more information, contact Bergoz or CERN.

## Access II: Use Version 1.2 With Apple IIGS

Revised: 10/4/89  
Security: Everyone

Access II: Use Version 1.2 With Apple IIGS

=====

This article last reviewed: 13 September 1989

TOPIC -----

I use Apple IIe and Apple IIc systems to communicate with my server HP by typing:

```
in#2
Control-A
T
```

at the Applesoft BASIC prompt.

When I tried this on an Apple IIGS, it didn't work. I set all communication parameters from the Control Panel exactly the same as the hardware settings on the Super Serial Card.

I tried starting up from a System disk, running BASIC.SYSTEM, and typing the program:

```
10 PRINT CHR$(4),"in#2"
```

```
RUN
```

This doesn't seem like a good permanent solution. Apparently, my version of Access II doesn't work on the Apple IIGS. Should I look for other terminal emulation software?

DISCUSSION -----

There should be no problem with this procedure on an Apple IIGS. You are invoking the Terminal mode from the Super Serial Card firmware, which should work.

The firmware may not be in modem mode. If this is the case, the method should

be Control-I T instead of Control-A T. (Control-I T is the command for the Printer/Terminal mode of the firmware, Control-A T is for the Modem mode.)

Access II does work on the Apple IIGS if version 1.2 is used.

Another terminal package is "ASCII Express MouseTalk" from United Software Industries.

Shareware terminal packages are available from various bulletin boards, but without a terminal package, accessing a bulletin board would be difficult at best.

For more information, search under: "United Software"

## AppleShare: Server Problems Using Removeable Media (9/94)

Revised: 9/13/94  
Security: Everyone

AppleShare: Server Problems Using Removeable Media (9/94)

=====

Article Created: 4 October 1989  
Article Reviewed/Updated: 13 September 1994

TOPIC -----

I'm having problems using optical disk drives as server volumes on AppleShare 2.0.1.

I'm using 350MB, double-sided media. The problems seem to occur when using this device as a slave drive for AppleShare (that is, not the startup volume). I wanted to get high-volume replaceable media on line.

But when attempting to change the media, I have found that AppleShare is a bit unreliable in recognizing and mounting the slave volume (even when it's been mounted previously).

The situations that arise are:

- Server acquires the volume but has to re-prepare it for use.
- Server does not find the volume at all.
- Server acquires the volume with no problems.
- On restarting the server, the system often responds with Bomb ID=01 or ID= 02, but the Resume button is active; clicking it causes successful continuation of the startup process.

In addition to the above, I once was not able to get the server to recognize the volume at all.

DISCUSSION -----

AppleShare File Server 2.0.1 is not designed to handle the changing of removable media while the server is active. This includes removable media of any type: CD-ROM, Optical Read/Write disks, Syquest hard disk cartridges, and so on. However AppleShare 3.0 allows you to change removable media.

During the startup of the server, each volume's AppleShare Parallel Directory

Structure (PDS) file is read. This allows the server to know which volumes are available for presentation to the user. The creation of the volume's PDS file requires the use of the AppleShare Admin application.

Launching the AppleShare Admin program from the Server Admin floppy disk causes Admin to examine each volume attached to the Macintosh server. If a volume is located that has not been prepared for AppleShare, the Admin program asks whether to skip the volume or to prepare the volume for AppleShare. Preparing the volume adds a Server Folder containing an AppleShare PDS file to the volume.

(On read-only volumes, like CD-ROM, the PDS file is written to the startup volume; otherwise, the PDS file is written to its own volume.)

AppleShare builds a separate PDS file for each on-line server volume that is not skipped. Since the PDS files are built only during the Admin program's preparation, and checked only during the server startup sequence, changing removable storage media while the server is active does not allow AppleShare to review the required PDS file for the newly inserted media. Therefore, the new storage media is an unknown volume to AppleShare and unpredictable results can occur.

The only procedure to assure that removable media is properly recognized involves shutting down the server, changing the media, then restarting the server. This allows AppleShare to read the PDS file for the newly inserted removable media.

NOTE: Check your INITs, too. The purpose of an INIT does not necessarily determine whether it causes problems. The specific actions taken within the INIT, and the relationship of those actions to other system functions, are the factors that may cause difficulty in the operation of the Macintosh.

In the situation describe above, AppleShare's procedure for working with on-line volumes, not the INIT, plays a larger part in the success or failure of the procedure. However, make sure the INIT gets installed before AppleShare begins verification of server volumes. This is easy to detect if the INIT displays an icon at startup time. If the icon appears during the "Welcome to Macintosh" screen, then the INIT has installed at an appropriate time. (INITs are installed by name, using the ASCII notation as a sorting guide.)

## Color Printers for the Apple IIGS

Revised: 10/4/89  
Security: Everyone

Color Printers for the Apple IIGS

=====

This article last reviewed: 13 September 1989

TOPIC -----

Are there any third-party vendors that make a color printer for the Apple IIGS?

I know the ImageWriter II prints color, and most Apple IIGS software talks PostScript.

I am interested in the HP PaintJet and other HP color printers, but I wonder if they can do the job: since they are not QuickDraw-compatible, most Apple IIGS software probably won't work.

DISCUSSION -----

With the advent of GS/OS for the Apple IIGS, printer communications follow a Macintosh-style architecture; both Macintosh OS and GS/OS printing are driver-based.

The print driver technique allows a wide variety of printers to be attached to the Apple IIGS -- once the driver is written. This allows Apple IIGS-specific applications to talk with the Print Manager. In turn, the Print Manager communicates with the Graphic Control Panel-selected print driver, which is installed in the Apple IIGS. Thus, the communication to printers relies on the availability of print drivers for the Apple IIGS, not on the specific application.

As shipped from Apple, GS/OS 5.0 provides direct connection drivers for the ImageWriter, ImageWriter LQ, and the Epson printers. For LocalTalk printers, LaserWriter, AppleTalk ImageWriter, and AppleTalk ImageWriter LPG drivers are included. Only the ImageWriter drivers provide color support; the Epson driver does not provide color capabilities.

Hewlett-Packard does not support the Apple IIGS-to-PaintJet (or other HP

printers) connection. Apple Tech Comm does not know of any third-party Apple IIGS print drivers that allow the selection of the PaintJet from the GS/OS Graphic Control Panel.

Orange Micro markets a product called Grappler C/Mac/GS. This is a serial-to-parallel converter. The Grappler device also provides ImageWriter II emulation for Epson, Okidata, Panasonic, and other Epson-compatible parallel printers. The Grappler C/Mac/GS can print in color on parallel color printers. We have been unable to define which of the following printers are color; however, Orange Micro has provided this list of Grappler C/Mac/GS-compatible printers:

- Epson : EX, FX, JX, RX, LX series; and the MX series with Graftrax
- Star : SD, SR, SG series; and Gemini 10X, NX-10 (in Epson FX mode)
- Okidata : 190, 290 series
- C.Itoh : C310XPR (Epson FX mode), ProWriter Jr.
- Panasonic: 1080, 1090 series
- Citizen : MSP-10 (Epson FX mode)
- Printers fully compatible with any listed above.

## MacDFT: Does Not Support Explicit Partitioning

Revised: 10/4/89  
Security: Everyone

MacDFT: Does Not Support Explicit Partitioning

=====

This article last reviewed: 13 September 1989

TOPIC -----

Does MacDFT support "explicit partitioning"? Apparently, it's a feature that is available on the new IBM 3290 Information Display Panel (gas-plasma screen). From what I understand, this hardware divides the screen and uses one data stream over coax to drive several sessions.

Does this make any sense to you?

DISCUSSION -----

Explicit partitions on the IBM 3290 screen allow up to four session windows to be displayed at one time. To define the session windows' size and location, a 3270 system extension, known as explicit partition, is used. Explicit partition sends a partition-structured field command from the host to the 3290 to tell the display the size and location of each session window.

MacDFT does not support explicit partitions. We are not aware of any third-party products that support this 3270 extension. However, MacDFT, when attached to a host's DFT port, can define a document with four windows positioned on the Macintosh screen. With this ability, MacDFT accomplishes the desired results of four sessions at once. This method places the session window management in the Macintosh, not on the host -- thus, allowing the host to concentrate on more important computing concerns.

## GS/OS: Making a Startup Disk With Printer Drivers

Revised: 10/4/89  
Security: Everyone

GS/OS: Making a Startup Disk With Printer Drivers

=====

This article last reviewed: 26 September 1989

TOPIC -----

I want to create a startup disk for GS/OS 5.0 that contains drivers for both a direct connect ImageWriter and a LaserWriter -- but even after reducing the number of resources on a startup System Disk by using the Installer, there is still insufficient disk space to install the LaserWriter drivers.

We didn't find any ideas on how to accomplish this task in The only solutions we found are:

- To remove drivers from the System Disk, which renders it nearly unusable (no P8, CDEVs, and so on).
- To recommend that the customer purchase a hard disk.

Is there another solution or minimum configuration that can be used.

DISCUSSION -----

"Chapter 5: Using The Installer" of the the Apple IIGS System Software User's Guide, version 5.0. (Apple part #030-1622-A) has a section on p. 99 called "Deciding What To Install", which discusses how to fit the desired parts of GS/OS onto a 3.5-inch disk for stand-alone Apple IIGS computers.

At the top of page 100, there is a paragraph referring the user to the "AppleTalk Network User's Guide for the Apple IIGS" -- which is included with GS/OS 5.0 -- for advice on how to install the required items for a networked Apple IIGS.

At the back of the AppleTalk Network User's Guide (Apple part #030-1633-A) is a four-page "Update to AppleTalk Network User's Guide for the Apple IIGS", which replaces "Creating a 3.5-Inch Networking Startup Disk" on pp. 24-26 of the network guide.

This update lists the procedures for:

- Using AppleShare File Servers, but not network printers.
- Using AppleShare File Servers and LaserWriter printers.
- Using one or two Types of network printers, but not AppleShare File Servers.
- Using AppleShare File Servers and ImageWriter or ImageWriter LQ printers.

Using the third procedure, substitute a direct connect ImageWriter for the AppleTalk ImageWriter used in the procedure. The resulting disk provides access to both the direct connect ImageWriter and the networked LaserWriter.

The disk will include:

Graphic Control Panel

DC Printer CDEV

LaserWriter CDEV

RAM CDEV

P8

Drivers for:

AppleDisk3.5

Console

Atalk

SCC

Printer port

ImageWriter

LaserWriter

with 11K still available.

This does not allow support of AppleShare file services. One of the printers needs to be discarded before file services can be provided. This is noted by the Installer during the installation procedure for AppleShare on a 3.5-inch disk. When AppleShare for 3.5 is selected, a dialog appears with the following message:

"WARNING: This update makes a 3.5-inch disk into an AppleShare disk. Files will be removed. Install any printer driver you want (only one will fit)."

(NOTE: Do NOT install this on your only copy of the System Disk.)

## Apple Monitors: Why Screen Flickers When Image Is Dragged

Revised: 10/4/89  
Security: Everyone

Apple Monitors: Why Screen Flickers When Image Is Dragged

=====

This article last reviewed: 26 September 1989

TOPIC -----

There seems to be a flicker in the Apple High-Resolution Monochrome Monitor and AppleColor High-Resolution RGB Monitor.

To produce the flicker, use MacPaint to create a black box approximately 1 inch by .5 inch. Then select the black box and move it from left to right. In one area of the screen (approximately the bottom one third), you will notice the black box flickering or breaking up as you move it.

This flicker also happens on some Macintosh SE screens (approximately the top one third).

What causes this?

DISCUSSION -----

The flicker is a result of non-synchronous timing between drawing the bitmap to the screen and refreshing the screen. It is a difficult programming task to synchronize the drawing of the image to the screen refresh rate. When this anomaly affects only the moving of selected images, the synchronization is often not implemented. When smooth animation is vital to the application's function, the problem generally does not occur.

The flicker can be seen with most bitmapped-based graphic applications (HyperCard, SuperPaint, MacPaint, FullPaint) that select an image and then directly drag the image. In applications like MacDraw, where only an outline of the image is moved, the flicker is not as evident.

The flicker has been reproduced with several combinations of applications and Macintosh models, and with a variety of monitors. Different combinations demonstrate the effect more prominently than others. We have unable to determine the exact reason certain areas of certain screens display this

effect more than others. Timing issues play a large part in this anomaly.

## Apple SuperDrive: User Guide (Part 1 of 3)

Revised: 8/23/91  
Security: Everyone

Apple SuperDrive: User Guide (Part 1 of 3)

=====

Article Created: 4 October 1989  
Article Last Reviewed: 23 August 1991  
Article Last Updated: 23 August 1991

TOPIC -----

This article, the first of three parts, contains suggestions for best use of the Apple SuperDrive (formerly Apple FDHD)

DISCUSSION -----

The Apple SuperDrive is a disk drive that can read and write in the standard Macintosh 400K and 800K formats, as well as the newer 1.4MB format. It also allows reading and writing 800K Apple II ProDOS, 720K MS-DOS, and 1.44MB MS-DOS formats.

(NOTE: The format used for MS-DOS is the same one used by OS/2.)

The SuperDrive uses 3.5-inch disks. These disks are available from several sources and come in three "flavors": single-sided (400K), double-sided (800K), and high-density (1.4MB). As a rule, the various disk types are guaranteed by the manufacturer to provide a certain level of storage per disk with little or no errors at the rated storage capacity.

The single-sided disk can be formatted to 400K, and the double-sided disk can be formatted as 800K with confidence (it can also be formatted to 400K). If you do format the 800K disk as a 400K disk, you lose about one-half of the disk's actual rated storage capacity. This may be useful if you want to pass data to a friend who has a Macintosh 512K or a Macintosh XL, which can read only 400K disks. You do not need to buy 400K disks -- just use your 800K disks formatted as 400K.

(Many single-sided disks are really double-sided disks that did not pass the factory's stringent testing standards for double-sided media, but passed as single-sided disks. So, other than the guarantee from the manufacturer,

double-sided and single-sided disks are manufactured with the same process.

High-density disks, however, are manufactured with a completely different process [different oxides, different rating of magnetic flux capacity per square inch, and so on].)

If you have a Macintosh that does NOT have the FDHD capability (like a Macintosh Plus), it is possible to take the high-density media and format it as a 400K or an 800K disk, but is NOT supported.

Unlike the double-density disk (800K), which can be formatted as 400K and be guaranteed to work as a 400K disk, there is no guarantee (especially from the manufacturers of the disk media) that the high-density (1.4MB) disk, when formatted as a 800K or 400K, will work as flawlessly as the user might expect.

The high-density media is a completely different media than is used in the single-sided and double-sided disks. Even the process to read and write information to the 1.4MB disk differs from the 400/800K modes of disk operation. A Macintosh configured for a SuperDrive as one of its floppy drives can tell the difference.

IMPORTANT NOTE: The Macintoshes that support SuperDrives include:

- Macintosh IIX
- Macintosh IICx
- Macintosh SE/30
- Macintosh SEs sold after August 2, 1989.

This article is continued in "Apple SuperDrive: User Guide (Part 2 of 3)".

## Apple SuperDrive: User Guide (Part 2 of 3)

Revised: 8/23/91  
Security: Everyone

Apple SuperDrive: User Guide (Part 2 of 3)

=====

Article Created: 4 October 1989  
Article Last Reviewed: 23 August 1991  
Article Last Updated: 23 August 1991

TOPIC -----

This article, a continuation of "Apple SuperDrive: User Guide (Part 1 of 3)", contains suggestions for best use of the Apple SuperDrive (formerly Apple FDHD).

DISCUSSION -----

(The Apple SuperDrive is a disk drive that can read and write in the standard Macintosh 400K and 800K formats, as well as the newer 1.4MB format. It also allows reading and writing 800K Apple II ProDOS, 720K MS-DOS, and 1.44MB MS-DOS formats.)

If you compare a 3.5-inch single- or double-sided disk to the 3.5-inch high-density disk, you will notice only small differences. There may be a difference in the disk labeling (whether it is silk-screened or ink-stamped), or the plastic jacket coloring, but the only two ways to spot the difference with certainty is that the high-density media have a "bonus hole" at the top of the disk and the letters "HD" on the front of the disk. The bonus hole is on the same end of the disk as the Write Enable/Write Protect tab, but on the opposite side. The letters "HD" are found around the shutter at the front face of the disk.

When you insert a 3.5-inch high-density disk into Macintosh computers without an Apple SuperDrive, which do not have the necessary mechanisms to detect the bonus hole, the computers presume that it is a "normal" single- or double-sided disk and try to operate with it as expected.

When the high-density disk is put into the SuperDrive-equipped Macintoshes, the SuperDrive senses the bonus hole and locks itself into the mode that allows the Macintosh to treat it as a 1.4MB disk. This is a hardware

function of the drive that cannot be overridden.

- If you insert and format a brand new double-sided disk into a SuperDrive-equipped Macintosh, the disk is formatted at a minimum of 400K or a maximum of 800K. The 400K format is interchangeable with all Macintoshes, and the 800K is interchangeable with all Macintoshes above the Macintosh 512K. So, going from the SuperDrive to the other Macintoshes, everything works just fine as long as you do not use the high-density disks.
- If you take a Macintosh Plus, insert a double-sided disk and format it, the best that you can hope for is 800K of storage on it. The Macintosh Plus then operates with the disk as expected (you insert the disk, the icon appears on the desktop. You can then open it, access applications and documents, and so on). If you take that same double-sided disk to the SuperDrive-equipped Macintosh and insert it into the SuperDrive, the SuperDrive does not sense the bonus hole, and therefore presumes that it is a 400K- or 800K-formatted disk. It reads the 400K/800K-formatted data off of the disk and all operates as expected -- just as on the Macintosh Plus.

Now, if you take that same Macintosh Plus, insert and format a high-density disk, you get a maximum of an 800K-formatted disk. Take this high-density disk to the SuperDrive-equipped Macintosh and insert it into the SuperDrive. The SuperDrive now senses the bonus hole, and therefore presumes that it is a 1.4MB-formatted disk. It tries to read the information on the disk in the 1.4MB mode and sees nothing that it recognizes as 1.4MB type of information. It cannot read the 400K/800K format that the Macintosh Plus put on it in the 1.4MB mode, and therefore gives the user the dialog box stating that it is not a readable disk.

The user sees a disk that works fine in another Macintosh, but does not work in the SuperDrive-equipped Macintosh, and assumes that it is a SuperDrive failure problem. Rather, it is because the SuperDrive has some intelligence, and processes the disk types differently.

A fix for this problem, as well as other information, can be found in the conclusion of this article, "Apple SuperDrive: User Guide (Part 3 of 3)"

## Apple SuperDrive: User Guide (Part 3 of 3)

Revised: 8/23/91  
Security: Everyone

Apple SuperDrive: User Guide (Part 3 of 3)

=====

Article Created: 4 October 1989  
Article Last Reviewed: 23 August 1991  
Article Last Updated: 23 August 1991

### TOPIC -----

This article, a continuation of "Apple SuperDrive: User Guide (Part 2 of 3)", contains suggestions for best use of the Apple SuperDrive (formerly Apple FDHD).

### DISCUSSION -----

(The Apple SuperDrive is a disk drive that can read and write in the standard Macintosh 400K and 800K formats, as well as the newer 1.4MB format. It also allows reading and writing 800K Apple II ProDOS, 720K MS-DOS, and 1.44MB MS-DOS formats.)

### The "Fix" -----

If you put the original high-density disk back into the Macintosh Plus and copy the 800K data from the high-density disk onto an 800K- formatted double-sided disk, you can then put the double-sided disk into the SuperDrive, and the Macintosh with the SuperDrive will read the data properly.

The SuperDrive also has the ability to exchange data on disks between Macintoshes and 3.5-inch drive-equipped MS-DOS or OS/2 computers.

Here are some scenarios to help you understand the combinations of disk types, drive use, and supported (and unsupported) combinations between the two:

- A user on an MS-DOS machine that uses 3.5-inch disks takes a brand new double-sided disk and formats it to 720K. The user can copy his Lotus 1-2-3 spreadsheets from his hard disk to the newly formatted disk and remove the disk from the MS-DOS machine. The user can go to the

Macintosh, launch Apple File Exchange (AFE), and insert the MS-DOS disk into the FDHD. A listing of the contents of the disk, including the spreadsheet that the user wants to transfer to the Macintosh, appears in the AFE window. All behaves just as expected (well, at least, like the manual says it will).

- A user on an MS-DOS machine who uses 3.5-inch disks takes a brand new high-density disk and formats it to 1.44MB. The user can copy his Lotus 1-2-3 spreadsheets from his hard disk to the newly formatted disk and remove the disk from the MS-DOS machine. The user can go to the Macintosh, launch Apple File Exchange (AFE), and insert the MS-DOS disk into the SuperDrive. A listing of the contents of the disk, including the spreadsheet that the user wants to transfer to the Macintosh, appears in the AFE window. Everything behaves as expected.
- A user on an MS-DOS machine who uses 3.5-inch disks takes a brand new high-density disk and formats it to 720K. The user can copy his Lotus 1-2-3 spreadsheets from his hard disk to the newly formatted disk and remove the disk from the MS-DOS machine. (In this instance, the MS-DOS machine does not care whether the disk is high-density or not. It only "cares" that it moved the data successfully to the target disk.) The user can go to the Macintosh, launch Apple File Exchange (AFE), and insert the high-density 720K-formatted MS-DOS disk into the SuperDrive. The SuperDrive cannot read the 720K-formatted MS-DOS disk in the 1.4MB mode, and the Macintosh gives the familiar dialog box that it is not a readable disk, Eject or initialize".
- A user on an MS-DOS machine that uses 3.5-inch disks takes a brand new double-density disk and formats it to 1.44MB. (Note: although this may be possible, it is NOT a supported configuration.) The user should be able to copy his Lotus 1-2-3 spreadsheets from his hard disk to the newly formatted disk. The user removes the disk from the MS-DOS machine. The user can go to the Macintosh, launch Apple File Exchange (AFE), and insert the double-density 1.44MB-formatted MS-DOS disk into the SuperDrive. The SuperDrive senses that the disk is not a high-density disk (no bonus hole) and attempts to read the disk in 400K/800K mode. The SuperDrive cannot read the 1.44MB-formatted MS-DOS disk in the 720K mode, and the Macintosh gives the familiar dialog box that it is not a readable disk, Eject or initialize.

(By the way, the correct MS-DOS command to format a double-density disk to 720K in a 1.44MB disk drive is:

```
FORMAT A:/N:9 /T:80
```

This tells MS-DOS to format the disk in drive A: to 9 sectors per track and 80 tracks, which fits the specifications of the double-density media. If you typed only `FORMAT A:`, MS-DOS assumes that the disk is high-density and tries to format it to 1.44MB. This is not a supported configuration even though it may be physically possible.)

Summary

-----

When you use the SuperDrive, make sure that you are using the correct disk for the job that you are doing. There are only two rules to remember:

- 1) If you are exchanging disks with older Macintoshes, Apple IIs, or 720K formatted MS-DOS machines, use only single- or double-sided disks.
- 2) If you are exchanging data with SuperDrive-equipped Macintoshes or with 1.44MB-formatted MS-DOS machines (most PS/2 machines fit this description), make sure that you are using high-density disks (the ones with the bonus hole).

## Macintosh: Menu Manager and Printer Font Handling

Revised: 11/11/91  
Security: Everyone

Macintosh: Menu Manager and Printer Font Handling

=====

Article Created: 4 October 1989  
Article Last Reviewed: 11 November 1991  
Article Last Updated: 4 October 1989

TOPIC -----

Technically, is there any difference between the ImageWriter, ImageWriter LQ, and LaserWriter IISC fonts and the normal fonts (FONT, FOND, and NFNT resources)? Or, is the Font Manager just looking for the 2x, 3x, or 4x fonts and using them?

If it is the latter, how does the Menu Manager know the right font sizes? Is it considering what printer driver is used? If an ImageWriter LQ is connected and the same fonts are installed, it had to show different font sizes installed than if an ImageWriter II is installed! Is the Menu Manager just showing the right fonts for the screen and doesn't care about the output?

DISCUSSION -----

The fonts that come with the ImageWriter LQ and LaserWriter IISC are bitmap fonts, just like the fonts that come with the System Software. The only difference is that they come in larger sizes. The Menu Manager and the Font Manager do not behave any differently than normal.

The printer drivers, however, do have an affect on how the fonts are used during the printing process.

For example, if you have a document comprised entirely of Geneva 12, and you are printing to an ImageWriter LQ, the ImageWriter LQ driver attempts to locate Geneva 36 and scale it down to the same size as Geneva 12.

This is done to make the printouts look better. Doing the same thing with the LaserWriter IISC would result in the LaserWriter IISC driver looking for Geneva 48. The ImageWriter II driver would look for Geneva 24.

This is the only difference in the way fonts are handled in these systems.

## LaserWriter IINT: How To Set PostScript Interactive Mode

Revised: 10/4/89  
Security: Everyone

LaserWriter IINT: How To Set PostScript Interactive Mode

=====

This article last reviewed: 26 September 1989

TOPIC -----

It is possible to set the LaserWriter IINTX to interactive PostScript mode via DIP switch settings, but the LaserWriter IINT cannot be set to interactive PostScript mode through hardware DIP switches.

Is it possible through PostScript (batch mode) to set the LaserWriter IINT to an interactive mode?

DISCUSSION -----

Yes. Both the LaserWriter IINT and the the LaserWriter IINTX can be set to PostScript interactive mode via PostScript.

Use the PostScript procedure that selects PostScript interactive mode. Type "executive", followed by a return or line-feed, and the LaserWriter will be in interactive mode.

Control-D or the PostScript "quit" operator causes the LaserWriter to go back to batch mode.

For more information, see pp. 289-290 of the "PostScript Language Reference Manual", also known as the "Red Book" (Addison-Wesley, ISBN #0-201-10174-2).

## When ADB Keyboards Do Not Function Properly

Revised: 10/4/89  
Security: Everyone

When ADB Keyboards Do Not Function Properly

=====

This article last reviewed: 28 September 1989

TOPIC -----

What causes a keyboard to act sporadically on a given machine? I have a Macintosh IIcx, and any keyboard connected to it eventually begins to act strangely. It throws characters and mistypes them. When ports are changed, the same thing happens. Is there anything wrong with the system file?

DISCUSSION -----

We suspect that the problem resides in the logic board of this specific Macintosh. Since using the other ADB port on this specific board did not work, we suggest running diagnostics on the logic board. An alternative would be to replace the board to see if the problems remain. It is quite likely that the hardware that controls the Apple Desktop Bus is intermittently failing.

If this does not resolve the problem, you can try using the Control Panel and resetting parameter RAM. You should also set the keyboard settings to their slowest level and then back to the desired settings. Parameter RAM does contain settings that can affect the performance of the keyboard.

## AppleFax Modem: Two Modems Needed To Send Text Files

Revised: 10/4/89  
Security: Everyone

AppleFax Modem: Two Modems Needed To Send Text Files

=====

This article last reviewed: 28 September 1989

TOPIC -----

AppleFax Modems are fine for sending Faxes, but I would also like to receive text files.

Is there a way to save the file as text, short of importing the received paint file into OmniPage and converting it?

DISCUSSION -----

Fax technology was designed to send and receive a facsimile (photocopy) of a document quickly across long distances. The ability to manipulate the received document defeats the purpose of the facsimile concept, since a manipulated document is no longer a facsimile of the original.

The facsimile communication protocol does not transmit and receive text. This protocol is based on the transmission of a graphic image. A Fax document is composed of scan line information at a resolution of approximately 200 dots per inch. Thus, the data sent via a Fax machine/modem contains no computer-readable text -- it's only a graphic image of the original document. A character recognition application is necessary to translate the graphic image into text, which a computer can edit.

However, when communicating with a second AppleFax Modem, the AppleFax Modem has the ability to transmit and receive Macintosh disk files at Fax speeds.

Macintosh: System 6 Heap Size not an Issue With DAs

=====

Article Created: 28 September 1989  
Article Last Reviewed: 29 May 1992  
Article Last Updated: 29 May 1992

Note: The following information pertains only to system software version 6.0.X.

### TOPIC -----

I am concerned about the possibility of running out of system heap space under System 6 when using certain DAs (Desk Accessories). Is there a suggested method for increasing system heap size?

### DISCUSSION -----

System heap size is not an issue as far as DAs are concerned under System 6.

When MultiFinder is not active, DAs are loaded into the application heap. With MultiFinder active, DAs are open and closed via the DA Handler. The DA Handler loads the DAs into the system heap, whose size is automatically increased by MultiFinder, as necessary. When a DA is closed, MultiFinder reduces the size of the system heap.

## AppleShare PC: Printing To Shared LaserWriter

Revised: 10/4/89  
Security: Everyone

AppleShare PC: Printing To Shared LaserWriter

=====  
This article last reviewed: 28 September 1989

TOPIC -----

I am using AppleShare PC software with my IBM PCs -- I want to share LaserWriters between Macintoshes and PCs.

The problem is that I want to print dBASE IV and Harvard Graphics documents, and am limited by the list of document types Apple supports in the software. Do you have any solutions?

DISCUSSION -----

It sounds to us like you are not using AppleShare PC print services at all, but instead you are using the old PC LaserWriter Program that USED to come bundled with the card. Only in that documentation are application and file types mentioned -- they are only relevant with the PC Laserwriter Program. This program is no longer bundled with the card for a variety of reasons, including: lack of flexibility, supporting only select PC programs, and the need to quit from the application before you could print.

The PC LaserWriter Program lets you print files created with WordStar, MultiMate, Lotus 1-2-3, Microsoft Word, or other applications that create files in ASCII format or files prepared for printing on a Diablo 630 printer.

The AppleShare PC program lets those programs that produce PostScript output to print in pass-through mode, or emulates and translates output intended for any number of Epson printers (listed below). It also translates printer commands and information intended for Epson printers into commands for output to an ImageWriter.

If the program you want to print from cannot produce (PostScript or) LQ2500 output, configure the program to produce output compatible with one of the printers in the list that follows. Use the first compatible printer in the

list. The Epson LQ2500 command set is a superset of these printer command sets, and can use them as well:

- Lq2500
- LQ1000
- LQ800
- LQ1500
- EX series
- FX series
- LX series
- RX series
- MX series
- Epson printer
- Standard printer
- Draft printer

Though we don't have any experience printing documents from either dBASE IV or Harvard Graphics, since they both support Epson printers and Harvard Graphics outputs in PostScript, we know of no reason why they couldn't be printed using the AppleShare PC printing facilities.

## Multidisk Audio CD Player Controlled from Macintosh

Revised: 10/4/89  
Security: Everyone

Multidisk Audio CD Player Controlled from Macintosh

=====

This article last reviewed: 28 September 1989

TOPIC -----

Can a multidisk audio CD player be controlled from Macintosh?

These CD players are controlled by standard cordless remote controls. Are there any infrared controllers that can be connected to a Macintosh serial port?

DISCUSSION -----

We are not aware of any commercially available infrared controllers that connect to the Macintosh.

If someone is interested in building a controller, they should check a back issue listing in Byte magazine. Several years ago Steve Ciarcia published an article describing the construction of a programmable infrared controller in his Byte column, "Ciarcia's Circuit Cellar".

Another approach for controlling multiple audio CDs from the Macintosh is using up to seven AppleCD SC drives daisy-chained on the SCSI bus. These are individually controllable from HyperCard via the HyperCard CD Audio Toolkit available from APDA.

## Internet Router: Router Version Mismatch Field

Revised: 2/6/90  
Security: Everyone

Internet Router: "Router Version Mismatch" Field

=====

This article last reviewed: 28 September 1989

TOPIC -----

I recently installed the released AppleTalk Internet Router in a Macintosh IIX with:

- AppleTalk Phase 2 Upgrade Utility.
- An Ethernet card running EtherTalk 1.2, which is connected to a MicroVAX running AlisaShare. (No Macintosh system is directly on Ethernet yet.)
- A Token Ring card that goes to an MAU that includes a Macintosh IIcx and an IBM Model 30.

The printer port includes a small Internet of several Macintoshes and a LaserWriter IINTX. The modem port goes to a backbone of several AppleTalk Phase 1 Internets.

Everything seems to be working fine -- that is, I can see all the zones and access all the servers, including the VAX. However, under the Internet Router statistics, I am getting a lot of packet traffic for "Router Version Mismatch". Is that something that the Upgrade Utility is compensating for, or do I have something wrong?

DISCUSSION -----

The "Router Version Mismatch" field tells you how many AppleTalk Phase 1 RTMP (Routing Table Maintenance Protocol) packets that the AppleTalk Internet Router has received. This is not a problem as long as the machine the router is on is also running the AppleTalk Phase 2 Upgrade Utility.

(NOTE: This does not mean that additional packet traffic is being generated.)

AFE: Reading 720K MS-DOS Disk Requires SuperDrive

=====

Article Created: 4 October 1989  
Article Last Reviewed: 23 August 1991  
Article Last Updated: 23 August 1991

TOPIC -----

I have a Macintosh Plus and want to use Apple File Exchange and DataViz translators to read 720K MS-DOS disks.

Whenever I insert a disk, the Macintosh responds with the message that the disk is unreadable and asks if I want to initialize it.

The Macintosh Utilities User's Guide says: "The File Exchange Utility runs on any Macintosh computer that has a built-in 800K disk drive."

Why doesn't it work on a Macintosh Plus, but does work when tested on a Macintosh SE?

DISCUSSION -----

Apple File Exchange should run on any Macintosh computer with a built-in 800K disk drive.

The problem here is not AFE, but the disk, so the manual's statements about the File Exchange Utility are beside the point. It is not possible to read an IBM-formatted (MFM) 720K disk in a Macintosh 800K drive. Only the Apple SuperDrive (formerly Apple FDHD) has this ability.

The Macintosh SE you used for testing is able to read a 720K MS-DOS disk, it must have an Apple SuperDrive installed.

## Internet Router: Needs One EtherTalk Card To Run 1.2 AND 2.0

Revised: 2/6/90  
Security: Everyone

Internet Router: Needs One EtherTalk Card To Run 1.2 AND 2.0

=====

This article last reviewed: 28 September 1989

TOPIC -----

In the EtherTalk documentation, it mentions that I can run both EtherTalk 1.2 and EtherTalk 2.0 on the same machine until my migration is complete to AppleTalk Phase 2.

Do I need two EtherTalk Cards in the router machine to accomplish this?

DISCUSSION -----

No, only one EtherTalk Card is required to communicate in EtherTalk 1.2 and EtherTalk 2.0 packets on the same network.

Complete details on this, including installation, are in Chapter 3 of the "AppleTalk Phase 2 Introduction and Upgrade Guide". This document was included in the "LAN Minds, Volume 1" binder under tab 9.

## TokenTalk NB Card, OS/2 LAN Server, and SMB

Revised: 10/4/89  
Security: Everyone

TokenTalk NB Card, OS/2 LAN Server, and SMB

=====

This article last reviewed: 28 September 1989

TOPIC -----

I am able to connect my Macintosh to an IBM running MS-DOS and PC LAN 1.3, but I'm having problems with the system running the OS/2 LAN software.

I am trying to connect the TokenTalk NB Card to an OS/2 LAN Server and use the SMB File transfer, but I'm having difficulties. As near as I can tell, I am getting a connection to the OS/2 server but cannot perform file transfers.

I am using the SMB server desk accessory to add and to connect to the server, and it seems to be working OK. The OS/2 system's disk flashes while the connection is established, and then it just stops. When I go to AFE, the SMB server is no longer visible. Apparently, there is another level of security with the OS/2 system that is preventing a firm connection. Is there a workaround? Does Apple support OS/2 LAN?

DISCUSSION -----

The SMB File Transfer Utility can communicate with the SMB file servers implemented in the IBM PC LAN Program versions 1.2 and 1.3 and in the OS/2 LAN server. When adding SMB File Transfer Utility users to the OS/2 server, be sure to identify them as DOS users. The Macintosh SMB File Transfer workstation name must match the OS/2 user name exactly.

If no files or folders appear in the AFE window for any directory on an SMB server, there are three possible explanations:

- 1) You have no access privileges for that directory.
- 2) There are no files or folders within that directory.
- 3) SMB File Transfer cannot determine your access privileges for the directory volume. If this is the case, the SMB File Transfer assumes

that you have no access privileges for this directory.

To determine access privileges when communicating with the OS/2 LAN Server, SMB File Transfer requires that you have either all privileges (A) for the directory to which you connect, or that at least one file exists in that directory.

If you do not have the required privileges, the network administrator needs to create at least one file in the directory to which users connect. This file gives the SMB File Transfer the information it needs to determine your access privileges.

For more information about communicating with an OS/2 LAN server, please read the Update to Apple SMB File Transfer Utility User's Guide shipped with the TokenTalk NB Card.

## AppleShare PC 2.0: PCLAN Compatibility

Revised: 8/28/90  
Security: Everyone

AppleShare PC 2.0: PCLAN Compatibility

=====

This article last reviewed: 28 September 1989

TOPIC -----

I am trying to use a PS/2 Mod 70/25 as a bridge between a broadband-based PCLAN server and AppleShare. I need to be able to update files on an AppleShare server from an SMB server every 30 seconds, and AFE's SMB Transfer Utility can't handle this repetitive task.

I installed a DayStar Digital MCA LocalTalk card in the PS/2 along with AppleShare PC 2.0. Both printing and file services worked as advertised. When I issued a "net use" to start up the PCLAN program, I was disappointed. I got some obscure DOS message about "out of buffer memory".

Next, I reconfigured the system to load PCLAN first. When AppleTalk tried to load, I got an error message stating that the session was already bound. After reading the AppleShare PC Read Me file, I came to the conclusion that I was having an interrupt conflict over 5C. Can I change the interrupt in AppleShare PC 2.0?

My next adventure actually worked. I installed the DayStar software, and after changing the load order, I was able to mount both an SMB server and an AppleShare volume on the same machine. I was able to copy files back and forth, and this appears to give me what I need. However, I would feel better using Apple's software, if possible.

Can I get AppleShare PC and PCLAN to co-exist?

DISCUSSION -----

It is possible to configure AppleShare PC 2.0 to use different interrupts and DMA channels.

The card being used must first be configured via its hardware (DIP switches, and so on) to also use those different settings. Once you have the settings for

the card, you have a couple of options available to configure AppleShare PC 2.0 properly.

The first is described on pages 20 through 22 of the AppleShare PC 2.0 manual (Apple Part #030-3002-A), and involves using the configuration menus supplied for the hardware you are using.

The second method is to edit the NET.CFG file, which is created during the configuration process mentioned above. Appendix C of the AppleShare PC 2.0 manual describes the various entries in this file and the different possible settings. It is important to remember that the card being used must have already been configured for the settings you choose in AppleShare PC, or the software will not run.

This should -- no guarantees, unfortunately -- let the two networking packages coexist peacefully. As a final note, Appendix C also contains information on setting buffer sizes as well as the interrupts and DMA channels.

## Macintosh: Continuous Digital Sound Playback Limited by RAM

Revised: 10/4/89  
Security: Everyone

Macintosh: Continuous Digital Sound Playback Limited by RAM

=====

This article last reviewed: 28 September 1989

TOPIC -----

Is the maximum length of continuous sound that a Macintosh II, IIfx, or IIfx can play determined by RAM size or hard disk size?

Maybe I should put it this way:

Is there any software that is capable of moving sound from hard disk to RAM and Audio Output fast enough to play hundreds of megabytes of continuous music on the Macintosh? Do we need special hardware (like a NuBus card) to do this?

DISCUSSION -----

Most of the Macintosh applications that record and play back 8-bit internal Macintosh digitized sound have their limits set by the amount of RAM in the machine. There are some high-end, higher cost, 16-bit, CD-quality sound solutions available. One of these is Sound Tools from Digidesign. This solution includes a NuBus card, external hardware, and software for the Macintosh II.

For more information, search under: "Digidesign"

## LaserWriter Driver: Font File Distinctive Icons Lost

Revised: 11/5/91  
Security: Everyone

LaserWriter Driver: Font File Distinctive Icons Lost

=====

Article Created: 4 October 1989  
Article Last Reviewed: 5 November 1991  
Article Last Updated: 4 October 1989

TOPIC -----

The original LaserWriter drivers had a creator of LWRT and a bundle resource that gave a desktop icon to PostScript font files that had the LWRT creator and a type of LWFN or LWFn, as well as to Laser Prep files with a type of LROM and creator LWRT. The new LaserWriter driver has a creator of LWRR, as does the new Laser Prep.

So far, all the downloadable font files that I have seen still have a creator of LWRT. Therefore, when one rebuilds the desktop, the icons for the downloadable font files are lost unless one of the old LaserWriter drivers is available. I tried changing the creator of a font file to LWRR, but even rebuilding the desktop with a copy of the new LaserWriter driver on the same disk does not result in anything other than a blank, generic icon. Is there a trick I need to use?

DISCUSSION -----

Changing the font file's creator to LWRR should have worked. It turns out that there is an anomaly in the BNDL resource in the LaserWriter 5.2 drivers that keeps the necessary information from being copied to the Desktop file of a disk.

Specifically, the LaserWriter 5.2 BNDL resource specifies FREF resources of IDs -8185 and -8186 for the two types of downloadable font files. However, these FREF resources actually have resource IDs of -8189 and -8190. Since the BNDL entries do not agree with the actual resource IDs for each FREF, the information is not copied by the Finder to the Desktop file, and the file icons remain blank.

If you want the icons to appear as they should, you can use ResEdit to

change the resource IDs of FREF -8189 to -8185 and FREF -8190 to -8186.

## X.25 to LocalTalk: Performance Degradation

Revised: 10/4/89  
Security: Everyone

X.25 to LocalTalk: Performance Degradation

=====

This article last reviewed: 25 September 1989

TOPIC -----

Are there any performance degradations when transmitting from a X.25 network to LocalTalk?

DISCUSSION -----

LocalTalk speed is a factor of 4 to 100 times FASTER than X.25 speeds. LocalTalk is 230.4Kbps, whereas most X.25 access lines are 2400 to 19,200bps, with a maximum of 64Kbps. Therefore, going from a LocalTalk to X.25 link will show lower "performance" than LocalTalk to LocalTalk.

## MacX25: Number of Server Connections Supported (7/93)

Revised: 7/8/93  
Security: Everyone

MacX25: Number of Server Connections Supported (7/93)

=====

Article Created: 25 September 1989

### Article Change History

-----

07/07/93 - UPDATED

- To include new information.

### TOPIC -----

What is the practical, maximum number of MacX25 connections one server can open? Does the MacX25 server software require a dedicated machine?

### DISCUSSION -----

The maximum number of virtual circuits (VCs) supported is dependent upon the number of Serial NuBus cards used by the MacX25 server. Each card supports a maximum of 64 VCs. There is a maximum number of VCs supported by the MacX25 server itself of around 250 VCs. So if you configured a MacX25 server using 4 Serial NuBus cards, you could theoretically support  $4 * 64 = 256$ , or 250 VCs.

The actual number of users that can be simultaneously supported depends on:

- The speed of the line (2400bps or a rate from 9600bps to 64000bps)
- The usage pattern (terminal traffic vs file transfer)
- The LAN media (EtherTalk or LocalTalk)

The X.25 server can run in the background; therefore, you do not need to dedicate a Macintosh to run MacX25.

## LaserWriter II: Paper Jam Problem/Cure

Revised: 10/4/89  
Security: Everyone

LaserWriter II: Paper Jam Problem/Cure

=====

This article last reviewed: 28 August 1989

BEFORE YOU START: Familiarize yourself with the LaserWriter II Technical Procedures. Be sure to follow proper ESD procedures.

Problem: Even after the printed paper is delivered to the output tray, sometime the Delivery Sensing Lever (P/N 949-0186) may not return in place completely, causing the engine to sense it as a paper jam.

Solution: To ensure the lever returns to its proper position, the shape of the lever was changed. This occurred in the fall of 1988. Changing the delivery sensor lever will correct the problem. Use part number 949-0186.

The old lever has a single chambered counter weight near the sensor interrupt portion of the Delivery Sensor Level. The new version has a double chambered counterweight, at the same location.

## LaserWriter IINTX: Changing Typeface in LaserJet+ Emulation

Revised: 10/4/89  
Security: Everyone

LaserWriter IINTX: Changing Typeface in LaserJet+ Emulation

=====

This article last reviewed: 13 September 1989

TOPIC -----

I am using the IBM PS/2-30-to-LaserWriter IINTX in HP LaserJet+ emulation mode connection.

Everything works perfectly until I try to select a typeface according to:

```
ESC(s3T Courier
ESC(s4T Helvetica
ESC(s5T Times Roman
```

It doesn't work but according to your paper and the manual, it should. I created a text file called font2.txt, which contains:

```
ESC(s4T
```

Then I create a file called helv.bat containing:

```
type font2.txt > lpt1    %Sends ESC-code.
dir > lpt1                %Print text; in this case, the directory.
end                       %Sends Control-D to empty buffer.
```

I execute that file by typing:

```
helv
```

Everything is sent to the printer, but the same typeface is still printed. The printer accepts the escape code but doesn't do anything. What is wrong?

DISCUSSION -----

The reason you could not select the typeface you wanted has to do with the way

the HP LaserJet+ works with characteristics. You changed the typeface to Helvetica without specifying the "Proportional character spacing" characteristic. Because this is a high-priority characteristic, and you did not specifically ask for it, the printer pointed back to the typeface with "Fixed character spacing," which is Courier.

The escape sequence to make this work is:

```
ESC(s1P
ESC(s4T
```

Note that the escape sequence to select Fixed character spacing is ESC(s0P. Characteristics priority is described in the "HP LaserJet Technical Manual."

## SMB Server: Printing and Spooler Questions

Revised: 10/4/89  
Security: Everyone

SMB Server: Printing and Spooler Questions

=====

This article last reviewed: 13 September 1989

TOPIC -----

Does Apple's implementation of Token Ring allow access to IBM PC LAN server-based spoolers? In other words, can a Macintosh print to a LaserJet serviced by a spooler on an SMB Server? Can an IBM PC print to a LaserWriter II through the same configuration?

DISCUSSION -----

As of September, 1989, we don't know of any LaserWriter IINT/NTX spooler for an IBM PC LAN server, or any method of printing directly from a Macintosh to a LaserJet on an SMB server. The SMB File Transfer Utility, which is bundled with the TokenTalk NB Card, provides only file transfer and translation between MS-DOS files on the SMB file server and the Macintoshes on the Token Ring network.

To print a file from the Macintosh to the LaserJet, first transfer the file to the SMB server using SMB File Transfer. Then, the start the print job.

An IBM PC running TokenTalk can print directly to LaserWriter, if the LaserWriter is connected to a Macintosh running the Apple Internet Router and the AppleShare Print Server.

## Macintosh-to-TenNET Connectivity

Revised: 10/4/89  
Security: Everyone

Macintosh-to-TenNET Connectivity

=====

This article last reviewed: 13 September 1989

TOPIC -----

Does anyone know of a Macintosh product that lets a Macintosh communicate with a PC that is running 10Net. 10Net, from what I have been told, is a network package that runs on IBM PCs, but I can't find any information about it.

DISCUSSION -----

We were unable to locate 10Net. However, there is a PC-based product called TenNET from TenNET Communications. Their PC LAN is based on the 802.3 standard, supporting 1MBps on twisted pair and 10MBps on either thick or thin coax.

TenNet Communications suggests that their users use QuickShare by Compatible Systems for accessing any PC hard disk from a Macintosh. This software/hardware product connects a SCSI port from a PC to the SCSI port on the Macintosh. It also supports text and bitmap graphics translations.

For more information, search the Tech Info Library under "TenNET Communications" and "Compatible Systems."

## AppleShare 2.0: Desktop Manager and UnMounting Cartridge Disks

Revised: 10/4/89  
Security: Everyone

AppleShare 2.0: Desktop Manager and UnMounting Cartridge Disks

=====

This article last reviewed: 19 September 1989

TOPIC -----

I have some Videoworks/Director demos that rely on the AppleShare 2.0 Desktop Manager System file for some special file management functions. This file causes problems with removable cartridge disk systems, when ejecting one volume and mounting another.

An easy solution is to simply drag the Desktop Manager out of the System Folder. However, this means that you can't use these cartridge systems for different animation demos, unless you are willing to restart with the new cartridge in place. Do you have any other solutions?

DISCUSSION -----

Our guess is that you have a copy of the Desktop Manager in the System Folder of your startup volume. This INIT shipped with AppleShare and is intended to be used on the server but can be copied to and used with any Macintosh volume. With this INIT in place, you can't unmount any volume you mount at startup, unless you use special utilities as you mentioned above.

Removing the Desktop Manager from the System Folder of the startup volume should let you unmount volumes by dragging the volume to the Trash, as would be expected.

## Macintosh: Mini-8-to-RJ-45 Connection

Revised: 6/17/92  
Security: Everyone

Macintosh: Mini-8-to-RJ-45 Connection

Article Created: 19 September 1989  
Article Last Reviewed: 9 June 1992  
Article Last Updated:

TOPIC -----

I have an AT&T 6544 controller with RJ-45 connections, but no coax or RJ-11 installed. (Access to corporate VAX and IBM systems is through the AT&T.) How can I connect a Macintosh asynchronously to this device?

DISCUSSION -----

Our goal was to connect one of the 8-pin serial ports on the back on the Macintosh to an RJ-45 connector. To do this, you need some kind of adapter. We used an RJ-45-to-DB-25 adapter from Black Box Corporation; it doesn't require solder. The DB-25 adapter can be connected to a DB-8-to-DB-25 serial cable. Here are the Black Box part numbers:

- EVMAI: Apple II-to-ImageWriter cable (or use one of our cables)
- FA027: RS-232/RJ-45 modular kit, female

Note: Not all AT&T controllers are wired the same for RJ-45 connection, so there is no guarantee that this exact wiring scheme will work for you. However, it may give you a starting point. Follow these steps:

- 1) Test the wiring. (It's a good idea to use colors on the RJ-45 side to avoid confusion). In this case, the following scheme worked:

| RJ-45 pin |        | DB-25 pin |
|-----------|--------|-----------|
| -----     |        | -----     |
| brown     | -----> | 8         |
| green     | -----> | 2         |
| black     | -----> | 20        |
| red       | -----> | 3         |

- 2) Connect the pins on the RJ-45 connector directly to the pins of the cable and attach a breakout box. You can monitor signals first at the user site and make any necessary changes before you construct the adapter. (Once the connections are plugged into the adapter, they're hard to extract.)
- 3) When you've got the correct pinouts, construct the adapter accordingly and screw it together.
- 4) Plug the cable into the back of the Macintosh, the adapter into the cable, and the RJ-45 connection into the adapter for asynchronous access to the AT&T. This works with MacTerminal and Red Ryder (two emulations packages we use).

A/UX 1.1: Korn Shell and "rootksh" Problem Report

Article Created: 19 September 1989

### Article Change History

-----  
08/27/92 - REVIEWED  
• For technical accuracy.

### TOPIC -----

I have a problem with the Korn shell option that lets you edit and reuse commands: "set -o vi". Normally, if you type this in a Korn-shell, you can edit and reuse previous commands (see "A/UX User Interface" page 3-8) by pressing Escape and then "+" or "-" to scroll through your commands and edit them using vi-commands.

This works perfectly well except in one case. If you go to multi-user ("init 2") and log on as "rootksh", you can't go back to previous commands (after a "set -o vi"). You still have to type "i" (after an Escape) before you can enter commands. This means that the keyboard input is intercepted by that pseudo-vi editor and not all functions are allowed, although you should be in a normal Korn-shell. If you try to do "exec ksh" from there, you will have the same problem in that shell, but everything works fine if you start another Korn shell ("ksh"). If you do a "su rootksh", you don't have the problem.

You only have the problem (as far as I tested it) when you go to multi-user and log on as "rootksh". This seems to generate a shell that doesn't behave like other Korn shells. Is this normal? Is this a known Korn shell problem (I didn't test this on other UNIX machines)? Is this typical for A/UX?

### DISCUSSION -----

We have verified the problem that the particular "rootksh" login account cannot perform the Korn shell previous command function by issuing Escape and "-".

## NCSA Telnet 2.3 Release Notice (8/94)

Revised: 8/8/94  
Security: Everyone

NCSA Telnet 2.3 Release Notice (8/94)

=====  
Article Created: 10 November 1989  
Article Reviewed/Updated: 8 August 1994

TOPIC -----

NCSA Telnet version 2.3 Release Notice Macintosh version only (July 14, 1989).

DISCUSSION -----

NCSA (National Center for Supercomputing Applications) Telnet is a combined Telnet client and FTP server program for the Macintosh. It emphasizes a convenient, powerful, user interface and can be configured to match the characteristics of your TCP/IP hosts. We have included support for a wide variety of Ethernet options. Complete user documentation is available: printed or in Macintosh Microsoft Word format files. NCSA Telnet is in the public domain and is available via anonymous FTP or by placing an order.

Features included in version 2.3 of NCSA Telnet

-----  
DARPA standard Telnet  
Built-in standard FTP server for file transfer  
VT102 emulation in multiple, simultaneous sessions  
Tektronix 4014 graphics emulation  
Scrollbar for each session  
Domain name lookup with default domain suffix  
RARP for dynamic IP address assignment  
Full color support (PC and Macintosh II)  
Font and size support (Macintosh)  
MacBinary FTP transfer (Macintosh)  
Apple MacTCP support  
Screens larger than 24 lines supported  
Color Raster display protocol (ICR)

Hardware required for NCSA Telnet

-----  
Macintosh: Macintosh Plus, Macintosh SE, Macintosh II, Macintosh IIX, or

Macintosh IIcx with 1MB memory and System 5.0 or later.

An AppleTalk-to-Ethernet gateway, one of:

- FastPath from Kinetics Inc. and Kinetics gateway software or Stanford KIP (Croft) gateway software
- GatorBox from Cayman Systems and associated gateway software
- Alternate FastPath-compatible LocalTalk-to-Ethernet gateway

or

- EtherTalk software, combined with any of the following hardware:
- EtherSC or EtherPort SE or EtherPort II from Kinetics
- EtherTalk Card from Apple Computer, Inc.
- EtherLink/NB (3C543) or EtherLink/SE (3C563) from 3COM Corporation
- Nodem products from Adaptec.
- MacConnect NIA310 from Interlan, Inc.
- Alternate EtherTalk-compatible systems for the Macintosh

EtherTalk software drivers are generally bundled with the hardware.

Where to Get a Copy

-----

You can get a copy from any of the following:

- From a friend. The documentation, program and source code are in the public domain. Copy, modify, and distribute, as you wish.
- Anonymous FTP from: ftp.NCSA.uiuc.edu (128.174.20.50)

You may want to ftp the READ ME file(s) to determine which files to transfer to your home machine. In particular, only transfer the source (1MB) if you really want it, and only get the MacTCP version if you need it.

The Macintosh version consists of several files encoded with StuffIt and BinHex 4.0. For those of you with BinHex only, UnStuffit is provided in BinHex form. Download the selections you need with an ASCII transfer method (Kermit, NCSA Telnet) and extract the individual files. The documentation is in Microsoft Word 3.X format (not fast-saved).

- Disk or Tape

Disk copies and printed manuals are available for a small fee, which covers materials, handling, and postage. The anonymous FTP tape covers the contents of all disks. Orders are accepted only if accompanied by a check in U.S. dollars made out to the University of Illinois. You can get an order form by contacting:

NCSA Telnet Orders  
152 Computing Applications Building  
605 E. Springfield Ave.  
Champaign, IL 61820

- Archive Server

Electronic mail a request to archive-server@ncsa.uiuc.edu. Include in the subject or message a line with "help" and a line with "index". This is a controlled-access server that E-mails the distribution to you one segment at a time. It is slow, but gateways to BITNET and overseas. To save time for access to NCSA Telnet, also include a line with "index Telnet\_Mac".

- LISTSERV at Brown University (LISTSERV@BROWNVNVM)

To request a file from LISTSERV@BROWNVNVM, send a GET command:

GET filename filetype

The files currently available are:

| NCSA file              | LISTSERV filename | filetype |
|------------------------|-------------------|----------|
| -----                  | -----             | -----    |
| README                 | README            | MEMO     |
| Telnet.src.sithqx      | TELSRC            | PACKAGE  |
| Telnet.2.3.docs.sithqx | TEL23DOC          | SITHQX   |
| Telnet.2.3.sithqx      | TEL23             | SITHQX   |
| Telnet.mactcp.sithqx   | TELMTCP           | SITHQX   |

In addition, the current list is available in the file NCSA FILELIST. To stay within BITNET file size guidelines, TELSRC PACKAGE consists of the file Telnet.src.sithqx split into three pieces. They must be combined using an editor or file utility before running BinHex.

LISTSERV accepts commands either interactively or via mail. Interactive commands are sent as messages to LISTSERV@BROWNVNVM. For example, on an IBM VM system, the TELL command is used: tell listserv at brownvm get NCSA filelist. To send a command via mail, send mail to LISTSERV@BROWNVNVM (BITNET address) or listserv@brownvm.brown.edu (Internet address), and specify the command as the first line of text in the body of the mail.

#### Electronic Mailing List

Mail to telnet-request@ncsa.uiuc.edu to be added to the list of recipients. To post messages to the list, mail to telnet@ncsa.uiuc.edu.

#### Article Change History:

08 Aug 1994 - Removed Dove Computer from article.  
26 Jul 1993 - Company title updated from Adaptec, Inc. to Adaptec.

## ImageWriter LQ: ROM Upgrade Service Program

Revised: 10/4/89  
Security: Everyone

ImageWriter LQ: ROM Upgrade Service Program

=====

This article last reviewed: 20 September 1989

TOPIC-----

I have a small network of approximately 10 Macintosh II systems, all using EtherTalk Cards with thinnet wiring. The Ethernet network runs connects through a Kinetics FastPath to a PhoneNET network containing two ImageWriter LQs with LocalTalk PC Cards.

With the original ImageWriter LQ logic board with the ROM version 00 everything worked fine. The printer was available on the network from both the Ethernet side and the PhoneNET side. When the dealer installed a new "Reworked" logic board with a ROM version 02 was installed in the ImageWriter LQ, the Macintoshes could access the printer on the PhoneNET side of the network. However, the printers became invisible on the Ethernet side.

Do you have any suggestions for solving this problem?

DISCUSSION-----

There are problems like the one you described that occur as a result of the ImageWriter LQ ROM Upgrade. To solve the problem, a second service program will replace the main logic board with a newer version. The part number of the board is 661-0563. Use the 02 ROMs and driver version 2.0 for the best results.

## MacIrma 1.20: Use With MultiFinder

Revised: 11/10/89  
Security: Everyone

MacIrma 1.20: Use With MultiFinder

=====

This article last reviewed: 20 September 1989

TOPIC-----

I have a Macintosh II with 5MB of memory under MultiFinder, running System 6.0.2. I use a DCA MacIrma board for IBM host connectivity. When I print five to ten mainframe screens in a row, the system freezes and must be restarted. Background printing is on, and there is no AppleShare Print Server on the network. Do you have any ideas?

DISCUSSION-----

According to our local MacIrma expert, this is a known problem in earlier versions of the software. Make sure that you are using version 1.20 of MacIrma, and the problem should disappear. If the problem does not clear up, contact DCA, Inc. For more details, search the Tech Info Library under "DCA."

## Scanners for Macintosh Computers

Revised: 10/4/89  
Security: Everyone

Scanners for Macintosh Computers

=====

This article last reviewed: 20 September 1989

TOPIC-----

Do you have a list of available scanners that can scan color slides in 35mm, 6x4, and 6x6 formats? Whether the scanner is a flatbed, a video camera or other doesn't matter.

DISCUSSION-----

We located three scanners that have transparency scanning capabilities. They are the Sharp JX-450, the Howtek Scanmaster, and the Truvel TruScan TZ-3T family.

Using a video camera to scan flat objects usually induces a small amount of curvature due to the camera lens optics. This is not noticeable when a video camera is used for scanning three-dimensional objects. However, the curvature may become unacceptable when used with two-dimensional items.

Most people feel that using the transparency to create a high-quality photographic print and then scanning the print on a color, flatbed scanner to be a more efficient method. The Howtek Scanmaster, Truvel's TruScan TZ-3C family, and the Sharp JX-300 or JX-450 work well with this technique.

For more details, search the Tech Info Library under "Truvel," "Howtek," and "Sharp."

## AppleShare Print Server: Error Code -127 Problem Solved

Revised: 10/4/89  
Security: Everyone

AppleShare Print Server: Error Code -127 Problem Solved

=====

This article last reviewed: 20 September 1989

TOPIC-----

I am having trouble in my lab. It contains the following:

Server hardware: Macintosh SE  
File server: AppleShare File Server  
Print server: AppleShare Print Server  
Workstations: Macintosh SE

All the workstations are running System Software 6.0. A fatal error occurred so the print server tried to clean up before releasing the printer. I got Error Code -127

The workstation (the fourth one that was about to print) got the message:

Printing cancelled. A problem occurred while printing. Error -4100

What can I do?

DISCUSSION-----

We tested a similar configuration in two labs. The first runs System 6.0 and the second lab System 6.0.2. We have no problems in the second lab. When we exchanged some equipment between the labs, the first lab still had problems. Running System 6.0.2 in the first lab resolved the printer errors.

## TokenTalk NB Card Connector Issues

Revised: 11/10/89  
Security: Everyone

TokenTalk NB Card Connector Issues

=====

This article last reviewed: 20 September 1989

TOPIC-----

I have an IBM PS/2 attached to a Token Ring. Can the DB-9 connector be detached from the back of the PS/2 and connected to the TokenTalk NB Card in the Macintosh?

Also, what do you do about the different types of connectors, like the yellow and green color-coded connections? Is it true that using the wrong type (color-coded) connector may bring down the Token Ring?

DISCUSSION-----

If the DB-9 attached to the PS/2 is a Type 2 connector, everything will work correctly when connected to the TokenTalk NB Card. However, if the DB-9 connected to the PS/2 is a Type 3 connector, one issue exists. This concerns the size of the DB-9 being attached the PS/2. Some Type 3 DB-9 connectors may be too wide to fit the opening of the Macintosh card slot. Using either the Nevada Western or the Belkin Type 3 connectors designed specifically for the Macintosh resolves the issue.

Using the incorrect cable may induce problems within the Token Ring. The following list describes what various color coding symbolizes.

- Green cables indicate a normal (straight-through, pin-to-pin) cable. This is the standard Type 2 cable.
- A yellow (or possibly red) stripe on the cable indicates that the cable has a built-in Type 3 filter. Type 3 filters are used when phone wire is the physical layer of the Token Ring.
- A yellow cable indicates that the transmit and receive pairs are swapped in the cable. This cable is used ONLY when connecting two Token Ring repeaters.

- An IBM adapter card, which has a green DOT on it, indicates that this connection is for an adapter cable (a DB-9-to-Data Connector adapter cable).

For more complete information on Token Ring connectors, refer to the IBM document #GA27-3677-0x, Token Ring Planning Guide.

For more details, search the Tech Info Library under "Belkin" and "Nevada Western."

## AppleTalk: Zone and Performance Issues

Revised: 10/4/89  
Security: Everyone

AppleTalk: Zone and Performance Issues

=====

This article last reviewed: 20 September 1989

TOPIC-----

I have an Internet containing five networks with a total of 75 Macintosh systems using Hayes InterBridges as routers. All five networks are in a single zone to minimize user confusion.

Is there a performance loss doing this? Should I separate the networks into different zones?

DISCUSSION-----

Zones provide almost no performance benefit. Zones were implemented to provide a more convenient interface to the Internet for the user and network administrator. NBP lookups are faster with more than one zone. Other than that, there is no performance difference.

It would not be a good idea to have all the file servers or LaserWriters for one Internet within a single network. The following is an example of improperly designed Internet:

Network "A" contains 15 Macintosh systems. Network "B" contains four LaserWriter printers and 15 Macintosh systems. Both networks are connected to a backbone via routers.

Here is what happens during a sample printing operation:

Printing from a node on network A to a LaserWriter in network B:

- 1) The packets from the node on network A are sent to the network A router.
- 2) The packets are then sent by the network A router, over the backbone, to the network B router.

- 3) The network B router sends the packets to the destination LaserWriter on network B.
- 4) All packets sent by the LaserWriter giving the job status return to the node on network A, along the same path in reverse.

Printing from a node on network B to a LaserWriter in network B:

- 1) The packets from the node on network B are sent to the destination LaserWriter on network B.
- 2) All packets sent by the LaserWriter giving the job status return to the node on network B directly.

As you can see by the two examples, it is significantly more efficient to print to a LaserWriter within the same network, whether or not the LaserWriter is in the same zone.

When deciding what components to put into a network, keep the above information in mind. It also applies to other networked devices, like file servers, not just LaserWriters.

## EtherTalk 2.0: Allows Serial & AppleTalk Communication

Revised: 6/29/90  
Security: Everyone

EtherTalk 2.0: Allows Serial & AppleTalk Communication

=====

This article last reviewed: 20 September 1989

TOPIC -----

I am having some difficulty printing with the ImageWriter LQ.

I have an EtherTalk Card for accessing AppleShare servers and other network entities, and an ImageWriter LQ on the printer port. When using Chooser to select the ImageWriter LQ (instead of LaserWriter) and selecting the printer port, all AppleShare connections are destroyed.

I notice that the A-L Historical Listing of software (6/89) in the Tech Info Library shows ImageWriter LQ disks rev 2.0.1. Could it be that this problem has been addressed with Revision 2.0.1?

DISCUSSION -----

Actually, it has nothing to do with the ImageWriter LQ driver. The EtherTalk 1.0 (1.1 and 1.2, inclusive) drivers make it impossible to use the printer port when EtherTalk is selected and AppleTalk is turned on.

The EtherTalk 2.0 drivers have solved this problem by freeing the printer port for serial or non-AppleTalk communications.

We do have a resolution to the problem, however. Here are the steps:

- 1) Remove the EtherTalk 1.0 software using the EtherTalk 1.0 installer.
- 2) Install the EtherTalk 2.0 software using the EtherTalk 2.0 installer.
- 3) Copy the EtherTalk 1.0 ADEV into the System Folder of the target machine; the name of the file is "EtherTalk".
- 4) Remove the file called "EtherTalk2.0". This file is used only when connecting to an AppleTalk, Phase 2-based, EtherTalk network.

The ImageWriter LQ disks rev 2.0.1, mentioned above, refer to the revision of the disk and not the software on the disk. ImageWriter LQ 2.0 is the latest revision of the driver.

## TextEdit: Limits and Alternatives

Revised: 6/29/90  
Security: Everyone

TextEdit: Limits and Alternatives

=====

Article Created: 21 September 1989  
Article Last Reviewed: 29 July 1992  
Article Last Updated: 29 July 1992

TOPIC -----

I have developed an alpha version of an electronic mail system for a Sun 4 server running UNIX with Macintosh front ends. Documents are limited to approximately 32,000 characters, because of the 16-bit count in the text editor (buffer). I want the system to handle longer documents, and this brings up a couple of questions:

- 1) "Inside Macintosh Volume I," page 392, shows "teLength" as an integer (16-bit). Is this the variable in question?
- 2) Does System Software 7.0 implement longint (32-bit) count?
- 3) Is there a tool kit available for developers that would help in this effort?

DISCUSSION -----

- 1) TextEdit is able to handle text up to 32,767 characters long. This is a design or implementation limit. The "teLength" field just happens to reflect this limit. Remember, TextEdit was designed for limited text handling tasks; it was not intended to be the foundation for an editor or word processor.
- 2) TextEdit will still be limited to 32,767 characters in System Software 7.0.
- 3) There is a text-editor tool kit available from Symantec call "CAPPS" that is compatible with their Think C and Think Pascal products. DataPak Software has a product called "WP-Engine" that may also meet your needs.

# ..TIL04596-TextEdit-Limits\_and\_Alternatives\_(TA40522).pdf

## AppleTalk: Zone Design Issues

Revised: 10/4/89  
Security: Everyone

AppleTalk: Zone Design Issues

=====

This article last reviewed: 21 September 1989

TOPIC-----

This article discusses technical advantages exist for communications within a zone:

- 1) Is there a simplified routing algorithm used within a zone?
- 2) How much performance difference is there between intra-zone and inter-zone transmission (for a given physical Internet)?
- 3) Are there any downside tradeoffs to grouping several networks as a zone?

We have been told that it is generally best to assign each network to its own zone. However, the Kinetics FastPath 4 manual (page 1-13) says that "...it is fastest to communicate with devices that are within one's own zone", and "...zones should be based on network traffic patterns". Which is correct?

DISCUSSION-----

- 1) There is no simplified routing algorithm used within a zone as compared to routing to another zone. This is because all routing depends on node IDs, socket numbers, and network numbers.
- 2) In most situations, there is very little difference. NBP lookups are faster when communicating within a single zone. Other than this, there are no performance difference.
- 3) It depends: the Kinetics FastPath 4 manual is correct saying that "zones should be based on network traffic patterns". It is not a good idea to put several saturated networks within the same zone. Nor is it a good idea to have all the file servers for one Internet within a single zone. It is best to balance the Internet by leveling the traffic

across zones so that a single zone does not contain the majority of the network traffic.

The Kinetics FastPath 4 manual is not completely correct saying "...it is fastest to communicate with devices that are within one's own zone". This statement is correct if each network is its own zone and incorrect if several networks are within a single zone. This is the true because it is necessary to go through a router if Network A is communicating with Network B, whether or not they are in the same zone.

For more information, we recommend reading chapters 7 and 8 of "Inside AppleTalk".

Security: Everyone

Cellular Modems: Availability

=====

Article Created: 4 October 1989

### Article Change History

-----

02/12/93 - UPDATED  
• Vendor information.

### TOPIC-----

Do you know anyone who makes car phone modems?

### DISCUSSION-----

You have two options:

- 1) An internal cellular modem. This is more expensive. However, Fujitsu makes a mobile phone with a datalink option.
- 2) Use a data jack with any existing Hayes-compatible modems. The data jack serves as an gateway and does not interfere with the phone or the modem. It is independent to the modem baud rate. Data jacks costs about \$150 and are available from Cellab in Canoga Park, CA.

You might want to try the phone book in your area for distributors of these products. If you cannot find any information in your area, try the following distributors in Northern California: CelluTel of Palo Alto and Mobile Land in Fremont.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

## TCP/IP-to-VM Connect and Ethernet Cards for Mac II (8/94)

Revised: 8/8/94  
Security: Everyone

TCP/IP-to-VM Connect and Ethernet Cards for Mac II (8/94)

=====

Article Created: 10 November 1989  
Article Reviewed/Updated: 8 August 1994

TOPIC -----

I want to send TCP/IP protocols to VM in the IBM environment. I also want information on all Ethernet interface cards that can be used in the NuBus slots for the Macintosh II family. Also, can you explain the configuration for connecting a Macintosh II with an Ethernet interface to the VM system?

DISCUSSION -----

1) Here are names and phone numbers of some vendors who support Ethernet interface cards for the Macintosh II:

- Apple Computer, Inc.
- 3COM Corp.
- EMAC, A division of Everex
- Asante Technologies

For a more complete list of hardware and peripherals communications vendors, please consult a commercial publication, like "The Macintosh Buyer's Guide.

2) IBM has a TCP/IP family of products called The Laureate Series. The TCP/IP for VM product (part number 5798-FAL) uses an S/370 channel to attach to a variety of controllers for connection to the selected network. The network controllers supported are:

- IBM 8232 LAN Channel Station
- Series/1 with Realtime Programming System

The 8232 LAN Channel Station is a controller-type device that provides

attachment of Local Area Networks to a host via the S/370 channel. The LAN Channel Station unit supports one or two LAN Channel Controllers. Each LAN Channel Controller supports two LAN connections to a host channel. To be on a VM TCP/IP network over Ethernet, the Macintosh needs an Ethernet adapter, TCP/IP software, like NCSA Telnet or TCP/Connect from InteCon Systems Corp and appropriate Ethernet cables.

3) To get an asynchronous connection to a Macintosh, you have three possibilities:

- Mac3270, by Simware
- MacBLAST, by Communications Research Group
- RELAY Baton, by RELAY Communications

For more details, search the Tech Info Library using the above company names.

## LaserWriter 6.0 Driver: Internet Router Conflict

Revised: 12/16/91  
Security: Everyone

LaserWriter 6.0 Driver: Internet Router Conflict

=====

Article Created: 7 October 1989  
Article Last Reviewed: 2 February 1991  
Article Last Updated:

TOPIC -----

I think I have a conflict between the AppleTalk Internet Router and LaserWriter 6.0 drivers. When I send a job to the printer with the gray-scale option, the system crashes completely without any system ID error. It seems to work fine when the black and white option is selected.

DISCUSSION -----

The following diagram will help illustrate our answer:

There should be no problem with Macintosh A printing gray scale to the LaserWriter: we have successfully tested this with no problems.

Printing from Macintosh B to the LaserWriter with the LaserWriter 6.0 driver is not recommended, because it uses much more memory than the LaserWriter 5.2 driver.

Printing

-----

(Note that the following considerations refer to printing from the router machine. These considerations do not refer to a workstation printing, even if it reaches a printer through a router.)

- Avoid background printing on a router machine. When PrintMonitor opens a

printer driver, it uses up memory; the router desk accessory may then run out of memory.

- Do not try 32-bit color printing from a router machine.
- Be aware that the 6.0 LaserWriter driver uses much more memory than the 5.2 driver. Avoid using the 6.0 LaserWriter driver on a 1MB router machine. Also, avoid using the 6.0 LaserWriter driver, when running the router and the AppleShare File Server concurrently.

SuperDrives: "Bad Formatting" May Mean Disk Is High-Density

=====

Article Created: 4 December 1989  
Article Last Reviewed: 23 August 1991  
Article Last Updated: 23 August 1991

### TOPIC -----

On a few occasions, when I have formatted an 800K floppy disk on a Macintosh II or Macintosh SE, then tried to use it in a Macintosh IIfx, Macintosh IICx, or Macintosh SE/30, I received a dialog box stating, "This is not a Macintosh disk, do you want to format it?". Why?

### DISCUSSION -----

This message, asking if you want to format a disk, occurs if the floppy disk formatted in the 800K drive was a high-density disk. Check the disks displaying this problem to see if they have a bonus hole -- an extra hole at the top right corner of the disk. They are also marked as high-density disks. There have been cases where high-density disks were put in packages with 800K disks, so you might not even be aware that there are two different disks.

When high-density disks are put into an Apple SuperDrive (formerly Apple FDHD), the drive sees the bonus hole and knows that it is a high-density disk. It also sees that it was not formatted for 1.44MB and wants to do that.

The medium for the 800K disks is different than for the high-density disks, and data is written differently to each. Because of this, we suggest that if you have any high-density disks that have been formatted as 800K disks, copy the information from the high-density disks onto 800K disks. The high-density disks should then be re-formatted as 1.44MB disks.

For more information, read the three-part Tech Info Library article, "A Guide to Using the AppleSuperDrive". Search under: "SuperDrive"

## Apple IIfc Plus: How To Print to a LaserWriter IINT

Revised: 12/4/89  
Security: Everyone

Apple IIfc Plus: How To Print to a LaserWriter IINT

=====

This article last reviewed: 3 October 1989

TOPIC -----

I want to print to a LaserWriter IINT in Diablo emulation from an Apple IIfc Plus running AppleWriter v2.0.

I am having some difficulty making this configuration work. Can you provide the cabling, serial port, LaserWriter, and software information necessary?

DISCUSSION -----

We were able to successfully print from an Apple IIfc Plus to a LaserWriter IINT using the following method.

We copied the software (AppleWriter 2.1, in our case) to a 3.5-inch disk. We set up the LaserWriter IINT and set the switches to Diablo mode (SW1 DOWN, SW2 UP) and connected it to the Apple IIfc Plus with an Apple IIe Printer-8 cable (Mini circ-8-to-DB-25 cable) and a Modem eliminator (DB-25 Male-to-DB-25 Female). If you have an Apple IIe Modem-8 cable, it will also work correctly.

We started up the software and set the parameters on the Apple IIfc Plus serial port #1 to 9600 baud, 7 data bits, No parity and 2 stop bits. (Setting the port is done by using the Control-O menu, Option-J "Setting the Printer/Modem Interface", and entering 9600,7,n,2, Return.)

Load a file into AppleWriter and press Control-P, then np, to print.

The main reason you may have had difficulty printing with this particular hardware/software configuration -- given correct cabling -- is that you may have assumed the Apple IIfc Plus serial ports default to a usable baud rate, as have previous Apple IIfc systems.

When setting the Printer/Modem interface through AppleWriter, we noticed that the ports default settings are 0 baud, 8 data bits, no parity, and 2 stop bits.

This needs to be changed to the configuration listed above before you can print.

## ImageWriter II: Maximum Interface Cable Length

Revised: 12/4/89  
Security: Everyone

ImageWriter II: Maximum Interface Cable Length

=====

This article last reviewed: 3 October 1989

TOPIC -----

I want to have an ImageWriter II printer directly connected to my Macintosh modem port (as a non-AppleTalk device), but have the printer physically located several yards away from the Macintosh. What is the maximum cable length for connecting an ImageWriter II directly to a Macintosh?

DISCUSSION -----

Tech Comm has driven an ImageWriter/ImageWriter II at distances up to 12 feet without difficulty. The RS-232 standard specifies a maximum of 50 feet using the maximum voltage (+/-25V).

If one side of the output device is grounded, to convert the signal from RS-422 to RS-423 signalling, the printer should workable at (approximately) a maximum of 50 feet away.

(NOTE: Since most Macintoshes use the same output device, the 26LS30, this information is relevant for most systems.)

## GS/OS: SCSI Device Driver Error Message (1/94)

Revised: 1/6/94  
Security: Everyone

GS/OS: SCSI Device Driver Error Message (1/94)

Article Created: 4 December 1989  
Article Reviewed/Updated: 6 January 1994

TOPIC -----

After I updated from GS/OS version 4.0 to 5.0, I received a strange error message -- "SCSI DEVICE NEEDS TO HAVE DRIVER INSTALLED" -- when starting up or reloading the desktop from a ProDOS 8 application. If I press RETURN, I can continue as if nothing is wrong.

I have tried various software fixes, including completely reformatting my 20MB hard disk and reloading it, but I continue to get this error.

DISCUSSION -----

It's hard to be specific without knowledge of the exact procedures used during installation, or what type of hard disk is in use. However, the following are generally the reasons the error message is posted.

There's an option called "Install Everything Possible" in the GS/OS 4.0 Installer. If you choose this option, it's likely that the SCSI Hard Disk option gets installed as a part of the "everything possible" option.

GS/OS 5.0 uses the "Latest System Files" option to install the major portion of GS/OS -- GS/OS 5.0 doesn't have the "everything" option. This means that the "SCSI Hard Disk" driver installation must be selected independently of the System Files installation.

The "Apple IIGS System Software User's Guide Version 5.0" (Apple Part #030-1622-A) discusses troubleshooting in Chapter 9. Page 155 of that chapter states:

"SCSI device requires a driver. Please install the SCSI driver on boot disk and restart system."

This message indicates that you've connected a SCSI hard disk, but the current startup disk (or "boot disk" in computer jargon) doesn't include the "SCSI Hard Disk update." Press Return to continue starting up. When the Finder desktop appears, use the Installer to add the "SCSI Hard Disk" update to the current startup disk.

With GS/OS versions 6.0 and 6.0.1, you can still get the error message, and it still means that something is missing from the installation. SCSI drivers are still installed as separate items in most instances. If you have a SCSI device attached and you don't have a SCSI driver installed, you'll get this message.

LaserWriter Driver: Will Not Print To LW With Password

=====

Article Created: 4 December 1989  
Article Last Reviewed: 5 November 1991  
Article Last Updated: 4 December 1989

TOPIC -----

Can the LaserWriter IINTX set an "exitserver" password? Is an exitserver password insufficient to prevent settings from being changed?

DISCUSSION -----

The LaserWriter IINTX CAN have a password, and that password is sufficient to prevent settings in the LaserWriter from being changed.

More importantly, the only password in the LaserWriter family (PostScript) of printers is the system administrator password. If this password is set to anything other than "0", the LaserWriter will not work with the LaserWriter drivers from Apple. If the password is set to zero, the LaserWriter effectively has no password. The LaserWriter drivers expect the LaserWriter to have no password and will not print to a LaserWriter with a password.

## Macintosh Video Card: Modifying 8-Bit to NTSC Color Video

Revised: 12/4/89  
Security: Everyone

Macintosh Video Card: Modifying 8-Bit to NTSC Color Video

=====

This article last reviewed: 3 October 1989

TOPIC -----

I hear that there are pinouts available for a cable that will modify an 8-bit Apple Macintosh Video Card to produce conventional NTSC color video as an unsupported feature. What are they?

DISCUSSION -----

The information you are looking for is actually a CDEV/INIT and a documentation file. These are on AppleLink in a file called "32-Bit QuickDraw Demos" under the "Developer Services" icon. Here is the path:

Developer Services  
Developer Technical Support  
Macintosh  
32-Bit QuickDraw  
32-Bit QuickDraw Demos

The CDEV/INIT file is called "Macintosh II Video Utility", the documentation file is "Video Utility Read Me".

Here is the information included about the cable:

"You will need a special cable to connect an RS-170-compatible monitor (or VCR) to your Macintosh. One side must plug into the Apple Macintosh II Video Card. It must have a 15-pin male DB-15 connector. The other side must plug into your video equipment. Pin 5 of the DB-15 connector contains the RS-170-compatible monochrome video signal. Pin 6 is the shielding ground for this signal. Typically, you connect pin 5 to the central wire of your video cable, and connect pin 6 to the shielding braid."

"WARNING: It is possible to damage your video equipment and/or your Macintosh II by using an improperly constructed cable. If you are not familiar with

video equipment, you should not try to make a special cable!"

## Internet Router: AppleShare Print Server Memory Requirement

Revised: 2/6/90  
Security: Everyone

Internet Router: AppleShare Print Server Memory Requirement

=====

This article last reviewed: 7 October 1989

TOPIC -----

What are the memory recommendations for an AppleShare Print Server?

I know that you need at least 2MB in the machine to support up to five printers. Does more memory give you better performance? I want to run Internet Router software in the machine as well. (The server will be connected to the network with an Ethernet adapter.) What will this do to the memory requirements?

DISCUSSION -----

Additional memory allows the AppleShare Print Server to capture more printers. It does not provide any speed improvement that we know of.

Here are some considerations for running the Internet Router in the same machine:

- It is recommended that you use 2MB RAM to run the router and the AppleShare Print Server, or to run the router and a mail server package concurrently. As long as you have 2MB RAM, you can also run the router, the AppleShare File Server, and any single foreground application, such as the Print Server.
- Best use of memory can be obtained by minimizing the INITs and desk accessories that run concurrently with the router.
- Run the router in Finder. MultiFinder runs desk accessories in the system heap, so you are likely to run out of memory, since the router driver and any other concurrently running process also takes memory from the system heap.

The following considerations refer to printing FROM the router machine. These

considerations do not refer to a workstation printing, even if it reaches a printer through a router:

- Avoid background printing on a router machine.
- Do not attempt 32-bit color printing from a router machine.
- The LaserWriter driver 6.0 uses much more memory than the 5.2 driver.

## AppleTalk Phase 2: AlisaShare and PacerShare

Revised: 12/4/89  
Security: Everyone

AppleTalk Phase 2: AlisaShare and PacerShare

=====

This article last reviewed: 7 October 1989

TOPIC -----

Is it possible to run PacerShare without using AppleTalk for VMS 2.0?

I know that AlisaShare will run by itself (modifying the NETWORK parameter in the ATK\$ROOT:[APPLETALK.ALISASHARE]ASPARAMS.DAT file) but will that change allow the server to run on an AppleTalk Phase 2 or Phase 1 network? If running the server directly on Ethernet (without the AppleTalk for VMS bridge process), it will not allow the server to run under AppleTalk Phase 2.

DISCUSSION -----

From what we understand, the NETWORK parameter in the ASPARAMS.DAT file determines the network to which AlisaShare connects. A value of 1 specifies a virtual network configuration, and 2 specifies direct connection to Ethernet.

You will need multiple Ethernet controllers within a single VAX: one for the AlisaShare process, and the other for the AppleTalk for VMS process. This configuration allows a higher performance AlisaShare process connected directly to the Ethernet, while still allowing access to the AppleTalk for VMS virtual network. We see no relation of this parameter to the AppleTalk Phase 2 support.

PacerShare does not use AppleTalk for VMS, only AlisaShare does. Current versions of PacerShare and AlisaShare support AppleTalk Phase 1.

## TokenTalk NB Card: Type 1 Cable Interface

Revised: 12/4/89  
Security: Everyone

TokenTalk NB Card: Type 1 Cable Interface

=====

This article last reviewed: 7 October 1989

TOPIC -----

I need information on a type 1 cabling interface for Apple's TokenTalk NB Card.

DISCUSSION -----

Here's some information about type 1 cable:

- Two-stranded, AWG #22, shielded twisted pair, solid wire, heavy jacket.
- Supports up to 260 stations, 33 Multi-Station Access Units (MAU) per ring.
- Tested up to 16M bps.
- Maximum lobe length: 330 feet.

To connect to our TokenTalk NB Card, you also need a Token Ring Adapter cable, which is shielded twisted pair about 8 feet long. One end of this cable is the IBM data connector to connect to an MAU; the other end is a DB-9 connector to our TokenTalk NB Card.

## Macintosh II Family: Fan Regulator Voids Warranty

Revised: 7/2/92  
Security: Everyone

Macintosh II Family: Fan Regulator Voids Warranty

=====

Article Created: 7 October 1989  
Article Last Reviewed: 25 June 1992  
Article Last Updated:

TOPIC -----

I have heard of a small device that can be installed inside the Macintosh II power supply, with a remote temperature sensor mounted near the hard drive. The function of this device is to regulate fan speed based on internal temperature so that fan noise would be greatly decreased.

Does installation of such a device void Apple's warranty?

DISCUSSION -----

Installing such a device definitely voids the warranty.

We strongly discourage installing such a device because of, among other reasons, the differences in temperature within the housing versus where the device's temperature pickup is located. This would be compounded by the quantity and locations of NuBus cards, RAM, and whether there is a hard disk drive or multiple floppy drives installed.

## LaserWriter: Using 3rd Party Products To Restrict Access

Revised: 12/6/89  
Security: Everyone

LaserWriter: Using 3rd Party Products To Restrict Access

=====

This article last reviewed: 7 October 1989

TOPIC -----

I need a product that restricts access to a LaserWriter.

I know there is a hardware device that acts as a spooler and provides LaserWriter accounts for tracking printing, but I can't find any information on it. Do you know of this product? The main objective is to limit access to a LaserWriter. I know of the solution to change the type of LaserWriter via a PostScript code and then alter the LaserWriter file as well. If you know of any other software or hardware products, please let me know.

DISCUSSION -----

We were unable to find one product that would fulfill all of your needs. However, what you want to do can be accomplished by using three products together.

Shiva offers zone security: putting the LaserWriter in its own zone with restricted access solves part of the problem.

Farallon's Traffic Watch allows the user to calculate traffic volume and source for a particular node.

Apple's print server software gives the user a page count for each job.

This is a less than perfect solution, but it does give you the results needed.

## System 6 Chooser: Device, Name, Zone, Memory Limits

Revised: 12/4/89  
Security: Everyone

System 6 Chooser: Device, Name, Zone, Memory Limits

=====

Article Created: 7 October 1989  
Article Last Reviewed: 28 July 1992  
Article Last Updated: 28 July 1992

TOPIC -----

This article discusses device, zone, and name limits as displayed and controlled through the System 6 Chooser DA window (which would correspond to version 3.x of the Chooser itself).

DISCUSSION -----

The following information pertains to Chooser versions 3.x:

The Chooser DA window consists of five separate sections:

- 1) The device type list.
  - 2) The AppleTalk zone list (visible only if there are multiple zones).
  - 3) The user name box.
  - 4) The AppleTalk active/inactive controls.
  - 5) The available devices name list.
- 
- 1) The Chooser is able to display a maximum of 16 items in the Chooser device type list. This is the limit that is imposed by the Chooser itself, not by something interfering with the operation of the Chooser.
  - 2) The Chooser allocates memory for the zone list dynamically, up to 32K. Each entry in the zone list uses 1 byte of memory for each character in the zone name, plus 1 byte. The Chooser uses this extra byte as a length byte. For example, the 7-character zone name "My Zone" uses 8 bytes of memory: 7 bytes for the characters and 1 byte for the length byte. The maximum length of a zone name is 32 characters. A 32-character zone name uses 33 bytes of memory.

Based on this information, if every zone had a 32-character name, it would be possible to have a maximum of 992 zones listed in the Chooser (32K / 33 = 992.97, remove the remainder). The maximum number of zones that can be displayed in the Chooser is wholly dependent on the length of the zone names being used.

- 3) The user name can be a maximum of 31 characters.
- 4) This one is self-explanatory; it controls whether or not AppleTalk is active.
- 5) Determining the maximum number of visible Chooser device names:

System 5.x and 6.x Choosers allocate a 512-byte buffer for the Chooser's list of available AppleTalk network device names. Each name in the buffer is embedded in an AppleTalk Name Binding Protocol (NBP) packet received by the Chooser from the selected device type. The NBP packet is called a "lookup reply", and is sent in answer to the Chooser's lookup broadcast for the selected device. An example is the selection of the device type LaserWriter driver, and the displayed LaserWriter object names.

When the 512-byte buffer is filled, this sometimes causes various names in the Chooser selection window to appear and disappear. When selecting the LaserWriter driver in this situation, a LaserWriter disappears and another appears approximately once each 1.5 seconds. This happens whenever there are more names than the buffer can hold. Because the lookups are usually sent in a series, whenever a device does not fit on the display list, the first reply received from a previous lookup is removed and replaced with the name of the device that did not fit. This process continues for each following lookup broadcasted by the Chooser. While the display list is also limited to 32 names, this is never reached when displaying devices like LaserWriters, because even with 1 character per name, the buffer is filled when 22 LaserWriters are displayed.

If you encounter the constantly appearing and disappearing LaserWriter situation, you can either break the network up into zones containing smaller numbers of the particular device, or reduce the length of some or all of the device names.

The buffer space used by each returned AppleTalk device is the length of the NBP reply packet returned by the device to the Chooser's lookup.

#### NBP LaserWriter Lookup Reply Packet Definition

```
-----
Function and Tuple Count:    1 byte
NBP ID:                      1 byte
Network Number:             2 bytes
Node ID:                    1 byte
Socket Number:              1 byte
Enumerator:                 1 byte
Object Field Length:        1 byte
```

|                    |                                           |
|--------------------|-------------------------------------------|
| Object:            | length of name                            |
| Type Field Length: | 1 byte                                    |
| Type:              | 11 bytes for type "LaserWriter"           |
| Zone Field Length: | 1 byte                                    |
| Zone:              | 1 byte for zone "*" the NBP reply default |
| -----              |                                           |
| TOTAL              | 22 bytes + length of the LaserWriter name |

A calculation for determining the maximum number of visible LaserWriters in a zone:

Number of visible LaserWriters = trunc( $512 / (22 + (\text{sum of name lengths} / \text{Number of LaserWriters}))$ )

If the LaserWriter names are all the same length, the calculation is simplified to  $\text{trunc}(512 / (22 + \text{length}))$ . The mean calculation ( $\text{sum of name lengths} / \text{Number of LaserWriters}$ ) is not necessary in this case.

(NOTE: Trunc indicates that decimal values should be ignored. That is, a result of 12.8 indicates 12 LaserWriters.)

The calculation can be used for any other type of AppleTalk device, if the type length and the mean of the device names are known.

In Chooser 3.3.1 selecting the Apple LaserWriter driver displays:

| Mean Name Length | Max Number of Visible LaserWriters |
|------------------|------------------------------------|
| -----            | -----                              |
| 30               | 9                                  |
| 25               | 10                                 |
| 20               | 12                                 |
| 15               | 13                                 |
| 10               | 16                                 |
| 5                | 18                                 |

## Chooser: NBP LaserWriter Lookup Information

Revised: 12/4/89  
Security: Everyone

Chooser: NBP LaserWriter Lookup Information

=====

This article last reviewed: 7 October 1989

TOPIC -----

This article discusses the performance of NBP lookups by the Chooser.

DISCUSSION -----

Chooser broadcasts are performed when an AppleTalk device is selected from the Chooser.

In the case of the LaserWriter, the Chooser does an NBP lookup or a broadcast request every 1.47 seconds five times. At the end of each set of five NBP lookups, the LaserWriter begins another set of five NBP lookups. Each set corresponds to a unique NBP ID number.

The function of the ID and associated set of five NBP lookups is to allow for incomplete transmission of replies. The time period and retry values for AppleTalk devices are found in the -4096 GNRL resource of AppleTalk drivers. The LaserWriter uses \$0B05. This means 11\*8 ticks (Tick = 1/60th of second) for time intervals between lookups and five retries per NBP lookup or broadcast request.

## TokenTalk NB Card: Isn't Supported by Mac286, PC LAN Services

Revised: 12/4/89  
Security: Everyone

TokenTalk NB Card: Isn't Supported by Mac286, PC LAN Services

=====

This article last reviewed: 11 October 1989

TOPIC -----

I have a Mac286 and a TokenTalk NB Card installed in a Macintosh IIX. Can I access typical PC LAN services, such as NETPRINT and NETUSE, or any other services that might typically be supported from PC LAN?

DISCUSSION -----

The Mac286 card has no means of communicating with the TokenTalk NB Card or other NuBus cards, in general. Also, the PC LAN software has not been written to support the TokenTalk NB Card -- especially since it is not a PC bus architecture card, much less an IBM product.

## MacWorkStation 3.1: Interprets Semicolon as End of Command

Revised: 12/4/89  
Security: Everyone

MacWorkStation 3.1: Interprets Semicolon as End of Command

=====

This article last reviewed: 12 October 1989

TOPIC -----

Regarding MacWorkStation 3.1 (specifically version b6):

I am sending a D010 with a dialog ID and item ID (for example, D010 209;3;), where item ID 3 is an editable text field, to get the text. However, my text contains some semicolons, which MacWorkStation uses as an end-of-line marker!

How can I return all of the text, including all of the semicolons?

DISCUSSION -----

The only way you can send a semicolon and not have it interpreted as the end of a command is to have it enclosed within double quotes (";").

The MacWorkStation manual has the following example:

"This string contains a semicolon;"

The string you are sending must be the entire string parameter for that specific MacWorkStation command, although the command itself and any other parameters would be outside the quoted string.

## TokenTalk NB Card: Connecting to a 16MB Token Ring Network

Revised: 12/4/89  
Security: Everyone

TokenTalk NB Card: Connecting to a 16MB Token Ring Network

=====

This article last reviewed: 12 October 1989

TOPIC -----

Is there any way to connect Apple's 4MB cards to a 16MB Token Ring using a PS/2 as a source router?

DISCUSSION -----

Currently, there is only one way to connect a Macintosh II with the Apple TokenTalk NB Card to a 16MB Token Ring network.

You must use an IBM-compatible computer with 16MB and 4MB Token Ring cards installed as a bridge between the 4MB Token Ring network that the Macintosh II is on and the 16MB Token Ring network. The PC needs to run IBM's Token Ring Bridge Program and be dedicated to this bridging function. (This works because we support source routing.)

## LocalTalk PC Card: Using It for IBM PC-to-VAX Connectivity

Revised: 12/4/89  
Security: Everyone

LocalTalk PC Card: Using It for IBM PC-to-VAX Connectivity

=====

This article last reviewed: 12 October 1989

TOPIC -----

Is there any software for an IBM PC with LocalTalk PC Card that allows communication (terminal emulation/file transfer) with VAX machines not running AppleTalk for VMS and Alisa/Pacer -- that is, for example, a TCP/IP or VT100 emulation through LocalTalk ->Kinetics FastPath ->Ethernet?

DISCUSSION -----

We are not currently aware of such a product.

Since the LocalTalk PC Card sends AFP calls to access the AppleTalk network, you cannot use it without an AFP-compatible server running on the VAX.

You will probably achieve better performance by connecting to the VAX directly over Ethernet or -- if that is cost-prohibitive -- over an RS-232 serial connection using an IBM PC terminal emulation package.

## Macintosh: How To Convert Database Files

Revised: 12/4/89  
Security: Everyone

Macintosh: How To Convert Database Files

=====

This article last reviewed: 12 October 1989

TOPIC -----

I need to transfer database information to Microsoft Works from a Tandy system running an ENABLE-based program called Legis and a program called Q&A.

How can I do this?

DISCUSSION -----

We are not familiar with either Legis or Q&A. However, transferring information from one database to another can be accomplished via several different methods and is fairly straightforward regardless of the method used.

The object is to find a common link between the two systems and their associated databases. This may be matching file formats, a common file format, the ability to import data from a text file, or being able to read an incoming data stream.

For your account, you may be able to use a common file format, such as DIF or SYLK, or save the database information to a text file and use the import feature within Microsoft Works to retrieve the information. In either case, you should be able to move the file from the Tandy to the Macintosh via the Apple PC 5.25 drive and Apple File Exchange.

If the account does not have access to an Apple PC 5.25 drive, the database-generated text file also can be transferred between the systems using either PC MacLink or a direct serial connection with a terminal package running on both systems.

Another method of moving the information would be to use a network solution, like TOPS or AppleShare PC, making the database files available to everyone. Again, to make this a working solution, a common file format is necessary.

## Apple Scanner: Controlling the Lamp During Scans

Revised: 12/4/89  
Security: Everyone

Apple Scanner: Controlling the Lamp During Scans

=====

This article last reviewed: 17 October 1989

TOPIC -----

Is it possible to perform a scan with the Apple Scanner lamp off?

I am trying to scan some X-ray photographs. However, because they are photo-negatives, they are very dark, and the Apple Scanner lamp:

- 1) Is not bright enough to pick out the white detail.
- 2) Causes reflections off the shiny surface of the "acetate" film.

I can solve problem "1" by balancing a photographic lightbox on top of the Apple Scanner, but then I have to switch off the Apple Scanner lamp when scanning to prevent the reflections in problem "2".

Is it possible to control the lamp via software, or is it controlled by the Apple Scanner hardware? Can I simply remove the lamp from the Apple Scanner, or does it automatically stop operating when the bulb is broken or removed?

As a worst case, is it possible to modify the Apple Scanner board to switch the lamp on and off manually, and also fool the Apple Scanner into thinking that it is on?

DISCUSSION -----

It is possible to control the Apple Scanner lamp through the control flags in the scanner driver. However, in normal operation, this function is controlled exclusively by the AppleScan software, and any changes would require either a modification to the AppleScan software (not a solution supported by Apple) or writing a custom scanner application.

As an alternative, it is also possible to remove the lamp from the Apple Scanner and still be functional with the AppleScan software.

## AppleShare Print Server: Installing Server System

Revised: 2/6/90  
Security: Everyone

AppleShare Print Server: Installing "Server System"

=====

This article last reviewed: 17 October 1989

TOPIC -----

The AppleShare Print Server Administrator's Guide refers to a "Server System" that should be used when installing a server.

What happens when a user wants to set up a server on a 68030-based machine that needs System 6.0.3? This is not provided for in the Server Software package. Since the standard System Software is the only way to obtain System 6.0.3, could this cause problems?

DISCUSSION -----

When installing the AppleShare Print Server on a Macintosh 512Ke, it is important to install the System Software using the AppleShare Print Server installer disk. This guarantees that the AppleShare Print Server software is running in conjunction with System Software that supports both the Macintosh 512Ke and the Print Server software.

On the Macintosh Plus and later Macintosh systems, we recommend installing the System Software from a disk containing the most recent version of System Software available for that particular machine. For example, you should install System Software 6.0.3 for the Macintosh IICx. Then install the AppleShare Print Server software.

## Apple Internet Router: Memory Issues Using with AppleShare

Revised: 2/6/90  
Security: Everyone

Apple Internet Router: Memory Issues Using with AppleShare

=====

This article last reviewed: 17 October 1989

TOPIC -----

I have this configuration:

Macintosh SE/30  
Dove internal Ethernet card (note--internal card, not the SCSI box)  
AppleShare File Server  
AppleShare Print Server  
Apple Internet Router

All three applications are running on this machine.

- 1) With the AppleShare File Server and Printer Server and the Internet Router running, is 2MB the proper amount of memory for this configuration? Is there any benefit to having more?
- 2) Is this, in general, a recommended configuration? Can I expect the Internet Router to perform reliably on the Macintosh SE/30 with the Dove card? Are there any problems with the Internet Router on the Macintosh SE/30 with any Ethernet card?

DISCUSSION -----

### 1) Memory considerations

- 
- In general 1MB of RAM is sufficient for running the router. However, you should consider the following exceptions:
    - You must use 2MB of RAM when running the router concurrently with the AppleShare File Server. You can add memory beyond 2MB, but that only increases performance of the file server and not of the router. The reason is that the file server uses all additional memory for its RAM cache.

- It is recommended that you use 2MB of RAM to run the router and the AppleShare Print Server or the router and a mail server package concurrently. As long as you have 2MB of RAM, you can also run the router, the AppleShare File Server, and any single foreground application, like a print server.
- To avoid memory problems, do not use MacroMaker on a 1MB router machine.
- Be aware that having MacsBug (or any other debugger) active reduces the amount of memory available to the router. Do not run MacsBug on a 1MB router machine or on a router that is also running the AppleShare File Server.
- To avoid memory problems, do not use 32-Bit QuickDraw on a 1MB router machine.
- Best use of memory can be obtained by minimizing the INITs and desk accessories that run concurrently with the router.
- Because of the way MultiFinder runs desk accessories, we recommend that you run the router in Finder. MultiFinder runs desk accessories in the system heap. This means that when you use the router desk accessory under MultiFinder, you are more likely to run out of memory because the router driver and any other concurrently running process take memory from the system heap.

- 2) As long as you have 2MB of RAM, you can also run the router, the AppleShare File Server, and any single foreground application, like a print server.

The AppleTalk Internet Router was tested with a variety of third-party Ethernet cards, including Dove's. At this time, we cannot recommend their use in a Macintosh acting as a router because of driver anomalies.

## Macintosh IIci: RAM Requirements

Revised: 9/30/92  
Security: Everyone

Macintosh IIci: RAM Requirements

=====

Article Created: 17 October 1989

### Article Change History

-----

09/30/92 - UPDATED

- To include additional information on the use of burst mode with Fast Page Mode RAM.

### TOPIC -----

This article explains the RAM requirements of the Macintosh IIci. Part numbers for Apple labeled SIMM upgrades and service parts that meet these requirements are also included.

### DISCUSSION -----

The increased speed of the Macintosh IIci is primarily due to two factors. The first factor is the increased speed of the 68030 CPU and 68882 FPU. Those chips are clocked at 25 MHz in the IIci.

The second is that the Macintosh IIci support 68030 burst reads to the on-chip data and instruction caches.

The 256 byte 68030 data and instruction caches are each organized in sixteen lines of four long word entries. The 68030 can save cacheable instructions or data into these long word entries. When burst mode is disabled, it takes five processor cycles to fetch each long word entry into the cache. Each entry is read into the cache, one at a time, as needed. To fill an entire cache line would take twenty cycles (5 + 5 + 5 + 5 = 20 cycles).

When burst mode is enabled, the on-chip cache entries are filled one line at a time. It takes five cycles to fetch the first entry, but it takes

only two cycles to fetch each of the remaining three entries, resulting in a total of eleven cycles to fill the entire cache line ( $5 + 2 + 2 + 2 = 11$  cycles). This mode is sometimes referred to as the "5 2 2 2" burst mode.

To satisfy the timing requirements of the 25 MHz 68030, the IIci requires a RAM speed of 80 ns or faster. To satisfy the requirements for burst reads, the IIci requires RAM that has a Fast Page Mode access type. Fast Page Mode (FPM) is a RAM access type that is necessary to support the "2 2 2" portion of the "5 2 2 2" burst mode access.

The use of burst mode with Fast Page Mode RAM gives the processor a maximum RAM access rate of 36.36 MB/sec. That access rate is always true for bank B. For bank A, it is achieved only when not using the built-in video circuits on the logic board; using a NuBus video card.

The built-in video circuits use a video buffer in RAM bank A. The effect of the video RAM cycles can decrease the processor's access to bank A by as little as 6% or as much as 65%, depending on the type of video display in use. Larger displays and display modes with more bits per pixel have a greater effect.

You will obtain better performance when using the built-in video circuitry by installing the larger SIMMS in bank B. For example, in a 5 MB configuration, put the 256KB SIMMS in bank A and the 1 MB SIMMS in bank B.

Ultimately, maximum performance can be achieved by adding a NuBus video card (high end / co-processor type).

If RAM is used in the IIci that is slower than 80ns, or does not support fast page mode, the system will eventually crash. Most of the RAM SIMM modules that are 80 ns have a Fast Page Mode access type. As a result, it should be uncommon for users to unknowingly install RAM in the IIci that do not have this access type. However, it is likely that unknowing or curious users will install RAM SIMMs that are rated slower than 80 ns. In most cases, those users will find that the slower RAM may work for a short time, but the IIci unit WILL eventually crash with a serious system error.

There are several reasons why a Macintosh IIci will not always crash immediately on power up when slower RAM is installed. They include:

- Frequently, RAM speed is rated conservatively. As a result, a chip may actually be faster than it is rated under certain circumstances.
- Many of the RAM SIMMs that are available on the market for use in the Macintosh SE/30, II, IIcx and IIx, including some sold by Apple, are rated for 100 ns, which puts them close to the 80 ns requirements.
- RAM speed is higher in a cooler chip than in a warmer chip with the same rating. When the Macintosh is first turned on, the chips are cool. After the unit is turned on, the chips will heat up, which causes them to slow down.

The part numbers for Apple labeled SIMM upgrades and service parts that meet these requirements are listed below.

Finished Goods RAM Upgrade Packages:

| Finished Goods<br>Upgrade Size | Part Number |
|--------------------------------|-------------|
| -----                          | -----       |
| 1MB, 80 ns FPM                 | M0291LL/A   |
| 4MB, 80 ns FPM                 | M5952LL/A   |
| 4MB (Parity), 80 ns FPM        | M0294LL/A   |

Service Goods RAM SIMM Parts:

| Service<br>RAM Density  | Part Number |
|-------------------------|-------------|
| -----                   | -----       |
| 256KB, 80 ns FPM        | 661-0519    |
| 1MB, 80 ns FPM          | 661-0520    |
| 1MB (Parity), 80 ns FPM | 661-0546    |

To identify 80 ns chips, some RAM manufacturers indicate RAM speed on the chip with a number that is usually expressed in tens. For example, 80 ns chips are marked with an 8, 100 ns with a 10, 120 ns with a 12 and 150 ns with a 15. When the speed is marked on the chip, it is usually set apart from the chip part number with a dash or is positioned in a separate location on the surface of the chip. Also, some SIMM manufacturers indicate the RAM speed on the back of the SIMM board.

For most of the SIMM modules that Apple sells, RAM speed can be identified with one of the above methods. However, RAM speed of some third-party SIMM modules are not so explicitly marked on the chips or the SIMM board.

Identifying RAM that supports fast page mode is more difficult, because this characteristic is usually not explicitly printed on the chip or the SIMM board. In most cases this will not be a problem, because the vast majority of the 80 ns DRAM SIMM can be installed into a IIci support Fast Page Mode.

Although both of these pieces of information can be confirmed in the chip manufacturers' data book, most people will prefer to contact the SIMM vendor to verify that the modules are compatible with the IIci. Customers should avoid purchasing SIMMs that cannot be confirmed to be IIci-compatible.

Many of the 256KB SIMM modules for the IIci will look different from the SIMM modules that we are accustomed to. Until now, Apple labeled RAM SIMM modules have contained eight RAM chips (8 chips x 256K x 1-bit each). Most of the Apple labeled 256KB, 80 ns, fast page mode RAM SIMMs will have only two RAM chips (2 chips x 256K x 4-bits each). Each SIMM module contains 256KB, but each chip contains four bits of each byte, instead of just one bit.

The 256K x 4-bit chips were chosen because 256K x 1-bit, 80 ns, fast page mode chips are not readily available.

## Macintosh IIci: RAM SIMM Configurations

Revised: 7/9/92  
Security: Everyone

Macintosh IIci: RAM SIMM Configurations

=====

Article Created: 17 October 1989  
Article Last Reviewed: 8 July 1992  
Article Last Updated:

### TOPIC -----

This article discusses the different RAM SIMM requirements presented by the Macintosh IIci, and provides the RAM configurations that the IIci supports.

### DISCUSSION -----

In all previous Macintosh models that have RAM SIMM slots, there were configuration requirements that dictated the following:

- All SIMM boards within a bank must be the same density.
- Within a bank that contains RAM, all four slots in that bank must be filled.
- All SIMM boards must be installed in Bank A for configurations that fill only one bank.
- Higher density SIMM boards must be installed in Bank A for configurations that have different densities in each bank.

In the IIci, the first two restrictions still apply. However, the second two are not requirements for IIci RAM configurations. These restrictions have been eliminated, due to functionality provided by the Memory Decode Unit (MDU).

Following are the valid RAM configurations supported by the Macintosh IIci:

(SPECIAL NOTE: Some of the RAM configuration recommendations that are

made below will be in direct opposition to configuration requirements on all previous modular Macintosh models.)

- 1MB: Four 256KB SIMMs can be installed in either bank. However, the built-in video feature requires that the RAM be installed in Bank A. If the memory is installed in Bank B, built-in video will be disabled, but the IIci will work fine.
- 2MB: Four 256KB SIMMs are installed in each bank.
- 4MB: Four 1MB SIMMs can be installed in either bank. However, the built-in video feature requires that the RAM be installed in Bank A. If the memory is installed in Bank B, built-in video will be disabled, but the IIci will work fine.
- 5MB: There are two possible 5MB configurations. The preferred is to install four 256KB SIMMs in Bank A, and four 1MB SIMMs in Bank B. This configuration is preferred because it minimizes the effects of video cycle stealing. The second is to install the 1MB SIMMs in Bank A and the 256KB SIMMs in Bank B.
- 8MB: Four 1MB SIMMs are installed in each bank.

4MB SIMM modules when available, can be used in the IIci. All of the above recommendations and requirements will still apply.

## EtherTalk Card: Problems with Macintosh IIcx/IIci

Revised: 7/2/92  
Security: Everyone

EtherTalk Card: Problems with Macintosh IIcx/IIci

=====

Article Created: 17 October 1989  
Article Last Reviewed: 26 June 1992  
Article Last Updated:

TOPIC -----

This article discusses the EtherTalk card (Revisions J and earlier) and its timing problem with Macintosh IIcx and IIci units.

DISCUSSION -----

Revisions J and earlier of the EtherTalk card have a timing problem with Macintosh IIcx and Macintosh IIci units.

Symptoms of the problem are intermittent, and include: system hangs on boot, serious system errors, and exceedingly poor network performance.

Revisions K and later of the EtherTalk card have been modified so that they will not exhibit this problem.

The capacitance of a six-slot NuBus was factored into the timing mechanism of the EtherTalk card. Consequently, the capacitance level in a three-slot NuBus is lower, thereby effecting the EtherTalk card's timing.

As additional NuBus cards are installed into a system, the capacitance level is raised on the NuBus. As a result, the problem is less likely to present itself.

The most likely Macintosh IIcx and Macintosh IIci candidates for having the symptoms mentioned above are units with a single EtherTalk card installed and no other NuBus cards in the remaining two slots. This is a configuration that would be commonly used for routers, file servers, mail servers, and so on.

The only current solution is to use EtherTalk card revision K or later.

## LaserWriter II: Using with Windows 2.11

Revised: 3/4/90  
Security: Everyone

LaserWriter II: Using with Windows 2.11

=====

This article last reviewed: 2 November 1989

TOPIC -----

This article discusses the correct version of Windows to use with a LaserWriter II

DISCUSSION -----

Microsoft Windows, used in conjunction with a LaserWriter II, sometimes has a problem of seeing ROM version I instead of PostScript 47, and thus refusing to print to it.

As of November, 1989, Microsoft UK has informed us that the latest versions of Windows (v2.11) and its PostScript driver (v3.1) do not suffer from this problem and will print to a LaserWriter II successfully.

## AppleShare File Server: Setting Up Using an Apple IIGS

Revised: 2/6/90  
Security: Everyone

AppleShare File Server: Setting Up Using an Apple IIGS

=====

This article last reviewed: 20 October 1989

TOPIC -----

I am having problems upgrading AppleShare File Servers with the new Apple IIGS System 5.0 software.

Here is what happens when I try to use the server:

- 1) When using the AppleShare on a 3.5-inch disk, everything works fine. I can log on, launch applications, save to the file server, print to the network printers, and log off the server by pressing ESCAPE.
- 2) When using either AppleShare with No Finder disk or self-booting over the network, I encountered the following situations:
  - a) The administrator can use the server as usual.
  - b) When trying to log onto the server as a user, after I type a name and password, GS/OS begins to load, then crashes with the following message:

"Sorry, system error \$004E occurred while loading the start FST file. Restart."

After further tests, I found that I can log onto the network as a user only after the administrator has previously logged on and used the Quick Logoff feature.

I tried reinstalling the updates, but the problem persists. What's going on?

DISCUSSION -----

The problems you report are most likely caused by not setting folder access privileges correctly on the AppleShare Server. For users to start up a workstation over the network, they must have See Files and See Folders

privileges for both the GS/OS System and Icons folders and all folders within the GS/OS System Folder. Note that we mean the GS/OS system folder named "System", and not the Macintosh "System Folder" or "Server Folder".

If you installed the GS/OS files on the server as the user Administrator, then starting up as Administrator should work properly, because Administrator is the owner of all the files and has complete access. When you start up as any other user with different privileges, it fails, because that user cannot access any or all of the necessary GS/OS files.

The usual problem is not setting privileges on the folders within the System Folder or missing the Icons folder completely. From the error you describe, it sounds like you need to select the "Change all enclosed folders" option when setting the privileges for the System Folder. With this option selected, all folders within the System Folder will be updated to use the same privileges as the System Folder.

The reason other users could log on after the Administrator had previously started up and used Quick Logoff is that all of the necessary files have already been loaded into the Apple IIGS. Using Quick Logoff doesn't clear them from memory; therefore, when the next user logs on, there is no need to access those files.

## HyperCard: Error 1277

Revised: 12/4/89  
Security: Everyone

HyperCard: Error 1277

=====

This article last reviewed: 20 October 1989

TOPIC -----

I keep getting HyperCard error 1277 when I try to add a new card, even though there is enough hard disk space to add a new card. What could the problem be? Is there a list of HyperCard error codes where I could look this up?

DISCUSSION -----

Error 1277 generally occurs when HyperCard tries to allocate space for an additional object and can't. It's usually the result of a corrupted stack. Our only suggestion is to use the recovery utility available on AppleLink.

Error codes in HyperCard are not available in list form because the codes are considered confidential.

For more information, search under: "HyperCard" and "Recovery"

## AppleShare PC 2.0: Compatible with PCLAN

Revised: 8/28/90  
Security: Everyone

AppleShare PC 2.0: Compatible with PCLAN

=====

This article last reviewed: 20 October 1989

TOPIC -----

This article discusses a method that allows AppleShare PC 2.0 and PCLAN to coexist.

(Some people have had problems running both PCLAN and AppleShare PC at the same time on the same machine. Both PCLAN and AppleShare PC try to install a network redirector to intercept file system calls to network drives.)

DISCUSSION -----

To get AppleShare PC 2.0 and PCLAN to coexist:

You must load PCLAN first, then AppleShare PC 2.0.

However, you will get an error loading the REDIR.EXE and MINSES.EXE programs. The functions provided by these two modules are duplicated in the PCLAN program.

To solve this, edit the batch files created by the install program so that neither REDIR nor MINSES is loaded. You must run PCLAN first because its redirector is a superset of Microsoft's redirector included with AppleShare PC. AppleShare PC can use IBM's redirector, but IBM can't use Microsoft's.

(NOTE: A related question is whether or not PCLAN and AppleShare PC will run at the same time using the same Token Ring card. Unfortunately, version 2.0 of AppleShare PC will not -- IBM's PCLAN software doesn't "share" the Token Ring card.)

## AppleScan: Problem Enlarging Documents

Revised: 12/4/89  
Security: Everyone

AppleScan: Problem Enlarging Documents

=====

This article last reviewed: 20 October 1989

TOPIC -----

I need some information about how to enlarge a scan area using AppleScan 1.0.2. on a Macintosh II using System 6.0.2.

The manual instructions state that you only need to click on the percentage selector to change the output size. The manual states that you can increase the size up to 400%. This would be great, but I can't seem to get past 100%. Help!

DISCUSSION -----

The ability of AppleScan to enlarge and reduce images is based on the resolution of the scan. Page 196 of the "Apple Scanner Owner's Guide" outlines this relationship and states:

"The Reduce/Enlarge process works in tandem with the resolution you are using. Reduce/Enlarge changes the effective scan resolution, and the values you can choose vary depending on the resolution setting. If you reduce an image, the scanner detects fewer dots per inch; if you enlarge an image, the scanner detects more dots per inch."

If the scanned image resolution is set to 300 dpi, it is not possible to increase the size of the image. This requires the Apple Scanner to have a resolution beyond 300 dpi. However, if the scan resolution is set to 150 dpi, it is then possible to enlarge the scanned image to 200%, or, in effect, 300 dpi for the Apple Scanner.

The complete description of how Reduce/Enlarge works in conjunction with resolution is on pages 194 to 198 of the "Apple Scanner Owner's Guide".

## AppleShare 2.0 : CD-ROM Issues (3/94)

Revised: 3/10/94  
Security: Everyone

AppleShare 2.0 : CD-ROM Issues (3/94)

Article Created: 22 October 1989  
Article Reviewed/Updated: 10 March 1994

TOPIC -----

This article contains questions and answers about a number of CD-ROM issues and AppleShare 2.0. Most does not apply to AppleShare 3.0, or AppleShare 4.0.

DISCUSSION -----

Q) I've got an AppleCD SC running on my AppleShare server. When I run the Administrator to prepare certain large CDs (such as the Boston Computer Society CD-ROM, 300MB and tons of files) for use with the server, I always get a -127 error.

I have no problem preparing and publishing simpler CDs, such as EDUCORP's, but I cannot get the BCS CD-ROM prepared for publication. It seems as though I'm reaching some type of AppleShare limit when the desktop files are being prepared. What's going on?

A) We tested the Boston Computer Society Macintosh PD-CD v2 and v4 discs with AppleShare 2.0.1; both worked flawlessly. We, too, have "prepared" numerous CDs for use as server volumes without difficulty. AppleShare file handling limits are significantly greater than the number of files that can be stored on a compact disc (search in the Tech Info Library under "Macintosh" and "maximum number of files" to get a explanation of the number of files the Macintosh OS allows).

Error -127 is a DS error, which is the equivalent of a system error for the file system and is of little help in identifying this problem.

Possible sources of the problem:

- You might have some INITs causing a conflict.
- You might have a damaged copy of the AppleShare Administrator or

Server software, or an early version that doesn't support locked media.  
You should be using 2.0.1 or later.

- Your compact disc or discs may be damaged.
- The AppleCD SC or other hardware (logic board, RAM, server hard disk) may be malfunctioning.
- You are using old or damaged copies of System Software, AppleCD SC software, and so on.

Q) How can I control the order in which volumes (CDs and hard disks) appear in the scroll box when logging into AppleShare?

A) At the server, devices are displayed in Finder order: startup volume first, followed by SCSI drives in descending order of SCSI address, followed by devices connected via the drive port in the order returned by the getVolInfo call.

At the workstation, the devices are displayed in exactly the opposite order, placing the startup volume at the bottom of the list.

Q) It takes me a very long time to prepare a CD for use with AppleShare. Sometimes the Administrator runs for 3 to 4 hours, and only after that tells you that it already knew about the CD. Your only choice is "OK", and then it still doesn't want to mount anyway!

Isn't there a way to prepare the CD index/desktop/privilege files -- or whatever it does when preparing a CD volume -- offline, so the server doesn't have to be shut down for hours?

A) We agree that it can be frustrating preparing and mounting large CDs. Unfortunately, there aren't really any shortcuts or workarounds, aside from preparing a series of CDs at one sitting to minimize startup time at a later time.

Your difficulties mounting might be related to the above, or possibly the AppleCD SC might not be "online" when the AppleShare program starts up.

#### Article Change History:

10 March 1994 - Made the article specific to AppleShare 2.0. Most issues do not apply to later versions.

## A/UX: Available Removable Cartridge Drives

Revised: 8/28/90  
Security: Everyone

A/UX: Available Removable Cartridge Drives

=====

This article last reviewed: 2 November 1989

TOPIC -----

Is there a removable cartridge drive for use with A/UX?

DISCUSSION -----

We know definitely of two companies that sells a removable cartridge drive that works with A/UX.

Advanced Information Concepts sells a drive called the AIC SlimLine, a 45MB removable hard-disk cartridge system that has A/UX drivers, and SlimLine II, a dual cartridge system.

The AIC Slimline uses the popular Syquest mechanism and cartridges with their own proprietary software. Their optional A/UX compatibility software allows Macintosh OS and A/UX partitions to coexist on a single cartridge.

MicroNet also makes a vast array of drives and tape backups that can be partitioned to run under A/UX or Mac OS.

## Aristotle: When New Users Aren't Recognized

Revised: 12/4/89  
Security: Everyone

Aristotle: When New Users Aren't Recognized

=====

This article last reviewed: 23 October 1989

TOPIC -----

I set up an AppleShare network at a school. This network consists of one Macintosh SE/30 with 4MB RAM and an 80MB hard disk. There are 15 Apple IIGS computers set up as workstations over PhoneNET cabling.

On day 1, we input approximately 210 users (all in the student group except for one teacher). These all appeared in Aristotle, and we were able to set up classes (approximately 10 classes). Everything worked fine up to this point.

On day 2, we input approximately 12 more users. We put them into the Macintosh SE/30, assigned them to the student group, set their startup application, restored their startup access, and saved the users and groups. Aristotle, however, did not rebuild the user list to include these new people. We reinstalled Aristotle and AppleShare, and they still do not appear in Aristotle.

I have an identical setup at another site, so I do have experience with this system. I need a solution -- short of starting from scratch and putting all 227 users in again.

DISCUSSION -----

There are several different reasons why Aristotle may not recognize new users that are added to the AppleShare server. Here are a number of important factors to check:

For all users starting up GS/OS from the server:

- AppleShare privileges must allow the user to See Files and Folders in the GS/OS System Folder and all folders within it. If the startup application is set to "Finder", AppleShare privileges must allow them to See Files in the Icons folder.

For all users on Aristotle:

- All users who will be Aristotle teachers must have their primary group set to "Teacher".
- All users who will be Aristotle students must have their primary group set to "Student".
- A Teacher's AppleShare startup application can be set to "Management" or "Finder", depending on your preferences. The startup application for students can be set to "Display" or "Finder", but setting it to anything other than Display tends to defeat much of Aristotle's purpose. The startup prefix for all of these users should be set to the folder that contains their individual startup applications.

Also:

- AppleShare privileges for the Users folder on the server must allow the Owner, Group, and Everyone to See Folders, and the folder's group should be "Teacher".
- The individual folders for Aristotle students and teachers within the Users folder must have their AppleShare privileges set to allow the Owner, Group, and Everyone to See Folders and See Files, and the Owner and Group to Make Changes. Also, the Group of these folders must be set to "Teacher". This is most easily accomplished by setting each user's group at the same time you create the user.

The AppleShare File Server software creates user folders as users are created. If you assign a user to a group when the user is created, then the user's folder is assigned to that group also.

- The Aristotle folder, and all folders within it, must have their AppleShare privileges set to allow the Owner, Group, and Everyone to See Files and See Folders, and the Owner and Group to Make Changes.

Chances are, one of these setups is incorrectly set in your system.

## Macintosh IIfx: Calculating RAM Speed

Revised: 7/9/92  
Security: Everyone

Macintosh IIfx: Calculating RAM Speed

=====

Article Created: 24 October 1989  
Article Last Reviewed: 8 July 1992  
Article Last Updated:

TOPIC -----

Why is the RAM on the Macintosh IIfx 80ns? My own mathematical calculations suggest a required speed of 40ns for a 25MHz chip and no wait states.

DISCUSSION -----

Your math is correct: the 25MHz 68030 CPU clock has a period of 40ns per clock.

However, the minimum memory access cycle for Macintosh IIfx is two clocks, which means that there is at least 80ns between memory accesses (one wait state). The maximum number of cycles between memory accesses is five clocks (three wait states).

For example, the Macintosh IIfx performs a random read from DRAM in five clocks and a four long word burst read in 11 clocks -- five clocks for the first long word and two clocks each for the remaining three long words.

- 1st Long Word - 5 clocks or 3 wait states
- 2nd Long Word - 2 clocks or 1 wait state
- 3rd Long Word - 2 clocks or 1 wait state
- 4th Long Word - 2 clocks or 1 wait state

## LaserWriter IINT: How To Print from Sun 360 Under UNIX

Revised: 3/4/90  
Security: Everyone

LaserWriter IINT: How To Print from Sun 360 Under UNIX

=====

This article last reviewed: 2 November 1989

TOPIC -----

This article discusses how to print to a LaserWriter IINT from a Sun 360, under UNIX.

DISCUSSION -----

Here is a tip on how to get a LaserWriter IINT working with a Sun 360 system under UNIX.

The problem most often described is that the Sun provides PostScript to the LaserWriter, which begins imaging the job (green light flashing) but nothing further happens.

The cause of the problem is probably that the UNIX spooler was adding a header to the print job. After toggling the option off, the LaserWriter IINT should work as expected.

## AppleShare File Server: Increasing Speed Bottlenecks

Revised: 2/6/90  
Security: Everyone

AppleShare File Server: Increasing Speed Bottlenecks

=====

This article last reviewed: 2 November 1989

TOPIC -----

I am having performance difficulties using a Macintosh Plus as a network server.

The network is correctly set up, and the load is fairly low (that is, there are only about five users on it).

One possibility is that the problem is caused by using a CPU that is not fast enough for the high performance of the 140MB Rodime external drive. Macintosh IIX systems are often recommended as servers, even for small networks.

I would have thought that the bottlenecks would be the disk performance (all that jumping around to meet different requests) and network performance (particularly on LocalTalk), not CPU performance, and that small networks users would get better value for their money if they used the Macintosh IIX as workstation.

I understand that the drive has to be formatted on its target machine, and I understand that the transfer rate for drives is faster on Macintosh II machines than Macintosh SE systems (but still the network is a bottleneck).

Could you give me some advice on this?

DISCUSSION -----

Access time, CPU speed, and network throughput all affect the "speed" of a network. It's difficult to determine just which one of the three elements mentioned will result in the largest performance increase.

However, if you are restricted to LocalTalk, and already have the Rodime drive, the only way to improve the network performance is to use a faster CPU.

## RS-170 Versus NTSC Video Standards

Revised: 7/8/92  
Security: Everyone

RS-170 Versus NTSC Video Standards

Article Created: 2 November 1989  
Article Last Reviewed: 7 July 1992  
Article Last Updated:

TOPIC -----

This article contains information about the RS-170 monitor extension software for the Monitors CDEV.

DISCUSSION -----

RS-170 is sometimes described as "the interlaced 60Hz video signal standard used for broadcast video in America."

This statement is a little misleading. RS-170 has not been the broadcast video standard in the United States for more than twenty years. RS-170, drafted in 1957, is a video signal developed by the Engineering Industries Association as a standard for monochrome (black and white) television studio facilities.

RS-170 can be recorded using the "Video In" jacks of most video tape recorders. The Macintosh II Video Card can generate a signal that is very close to the exact specifications of the RS-170 standard--close enough so that it can be displayed on most RS-170 monitors, recorded on most RS-170 video tape recorders, and so on. Unfortunately, the minor deviations from the exact standard causes problems with some video equipment.

Twenty years after the drafting of RS-170, the EIA video signal standard proposal RS-170A evolved into what is known today as NTSC. NTSC is the color television standard of the National Television Standards Committee, and is the standard now used for broadcast video in America. This standard is the result of combining three RS-170 signals into a single encoded color video signal.

While RS-170 signals are compatible with most of today's NTSC video

## ..TIL04688-RS-170\_Versus\_NTSC\_Video\_Standards\_(TA40591).pdf

products, it is NOT broadcast video, NTSC video, or color video. Not knowing this fact can lead to confusion.

For more information, search for "Macintosh and Video Overview".

## Macintosh Portable and PowerBook: ADB Mouse Q & A 3/93

Revised: 5/16/94  
Security: Everyone

Macintosh Portable and PowerBook: ADB Mouse Q & A 3/93

=====

Article Created: 2 November 1989  
Article Reviewed/Updated: 03 March 1993

TOPIC -----

This article contains questions and answers about ADB mouse devices and the Macintosh Portable and the Macintosh PowerBook.

DISCUSSION -----

- Q) Can I use the low-power ADB mouse that is available for the Macintosh PowerBook (and originally shipped with the Macintosh Portable) with other computers in the Macintosh family?
- A) Yes, you can use the low-power mouse with ANY Apple computer that has an ADB port. It is equipped with a ferrite EMI filter in the ADB connector to meet EMC standards specifically for the Macintosh Portable and PowerBook.
- Q) Can I use a standard ADB mouse with the Macintosh Portable or PowerBook?
- A) There are two standard ADB mouse devices available. One of these is low-powered. You should not connect either of the standard mouse devices to the Macintosh Portable or the PowerBook. This violates the FCC specifications and would draw too much power if it was not the low-power model.
- Q) Is there any visual way I can distinguish between the mouse devices?
- A) Yes:
- The standard mouse has an ADB connector that is approximately 0.5 inch long.
  - The standard low-power mouse also has an ADB connector that is approximately 0.5 inches long and there is a low-power symbol (a half

circle with a dash across the top) on the product label.

- The low-power mouse has an ADB connector that is approximately 1 inch long and also includes the low-power symbol(a half circle with a dash across the top) on the product label.

#### Article Change History

-----

10/08/92 -Revised to include the PowerBook and clarify differences between the two low-power ADB mouse devices.

## Guided Tour System Disk Bombs

Revised: 12/4/89  
Security: Everyone

Guided Tour System Disk Bombs

=====

Article Created: 2 November 1989  
Article Last Reviewed: 1 June 1992  
Article Last Updated: 1 June 1992

TOPIC -----

Whenever I try to run a Guided Tour for an Apple peripheral I bought several years ago, my Macintosh freezes up. The System Folder on the Guided Tour disk, which I am trying to boot from, is 4.1.

DISCUSSION -----

You probably have a Macintosh which requires a more recent version of system software than was included on your Guided Tour disk. A workaround is, instead of booting from the Guided Tour floppy, to drag the Tour Folder from the Guided Tour disk to the hard disk. While still running under the System Folder on the hard disk, launch the tour by double-clicking on its icon (looks like a movie projector).

This workaround should work with several older Guided Tour disks, such as those for the Apple Scanner and the LaserWriter IISC.

## TokenTalk NB Card: Range of Burned In Addresses

Revised: 12/4/89  
Security: Everyone

TokenTalk NB Card: Range of "Burned In" Addresses

=====

This article last reviewed: 2 November 1989

TOPIC -----

I have two questions about the TokenTalk NB Card:

- 1) What is Apple's range of "burned in" addresses for the TokenTalk NB Card? I have a customer who has the IBM LAN Manager software and wants to identify the newly installed Macintosh systems by their addresses.
- 2) In the LAN Minds binders, there was mention of a CDEV that comes with MacAPPC and MacDFT that allows the identification and changing of the addresses associated with the TokenTalk NB Card. Can I have some more information?

DISCUSSION -----

- 1) The IEEE 802 committee has assigned Apple the address range of "5000E0000000" to "5000EFFFFFFF". This gives Apple over 268 million possible Token Ring network node addresses.
- 2) The CDEV in question is called "Token Ring" and will be included with MacAPPC but not with MacDFT. The MacDFT CDEV has all the functions of the Token Ring CDEV plus the MacDFT specific features.

## Apple II: Using a Switchbox With ImageWriter II

Revised: 12/4/89  
Security: Everyone

Apple II: Using a Switchbox With ImageWriter II

=====

This article last reviewed: 14 November 1989

TOPIC -----

I am having problems with my Apple II, switch boxes, and ImageWriter II.

What actually is the difference between the ImageWriter and the ImageWriter II?  
Is there solution guaranteed to work?

Do you know of anybody who is having success with ImageWriter IIs and switch boxes?

DISCUSSION -----

The workaround is to use XON/XOFF handshaking.

Following is an explanation of what happens when switching between an Apple IIGS and an Apple IIe. Also included is an explanation of why this may not be a problem with ImageWriters, and why a MicroBuffer may cure this as well.

Set-Up:

-----

Our configuration to test this problem was an Apple IIe equipped with a Super Serial Card, an Apple IIGS, and an ImageWriter II, along with two commercial switch boxes. Line status was monitored with a Data Specification RS-232 Break-Out box. A Fluke 8050A Digital Multi-Meter was used to measure the voltage levels. Software used was AppleWriter II with the same file open on both systems.

The Test:

-----

When switching between the systems, transitions were noted on the Transmit line, which caused DTR from the printer to go into the high state, effectively

shutting off communication with the connected computer. If the printer does a reset in between the systems, the now-connected system prints correctly. If there is no reset when switching, it is necessary to reset the printer by either deselecting/selecting, as you stated, or by powering off the printer, and powering it on again. Either of these actions resets the DTR line and re-establishes communications with the computer.

Our first thought was to use a switch box with a make-before-break switch. The reason this would not work with Apple IIe and Apple IIGS systems connected is the difference in voltage levels between the systems. The Apple IIGS system output device, AMD 26LS30, is supplied with +/-5VDC, while the Super Serial Card output device, TI 75189, is provided with +/-12VDC. This means that the Apple IIGS outputs -4.7 volts for a "Low" signal while the Apple IIe outputs -9.7 volts. When the switch is thrown from one position to the other, here's what happens:

With the switch type a break-before-make, when the switch opens between contacts, the voltage level rises to Ground, then drops to a Low level again. This positive transition to Ground causes the printer to see either a start bit or a DSR level shift from the computer, which then sets DTR false. If the switch box is a make-before-break switch, there would be current flow from the Apple IIe into the Apple IIGS output because of the different voltage level in the output "Low" signal, which could cause damage to the interface chips in the Apple IIGS.

XON/XOFF works because the printer sends/receives the XON/XOFF handshaking over the normal data communications lines, pins 2 and 3, and even though these lines are affected by the level transitions caused by the switch action, these transitions are not recognized as XON/XOFF by the printer or the computer. Because the equipment doesn't see these transitions as requests to halt data flow, there is no attendant response to incorrect data by the printer, and the information flow continues.

The ImageWriter has 75189 receiver chips installed, functionally equivalent to the 1489 Line Receiver, which are much less sensitive to level transitions because they are designed to operate at lower frequency limits. This causes them to be much more tolerant of the level transitions that occur during the actual time of the switch. ImageWriter IIs have 26LS32s for receivers. They are designed for higher speed use, and thus are much more sensitive to the level transitions occurring. This is our interpretation of why this problem does not exist with the ImageWriter.

A MicroBuffer might cure this problem because the ImageWriter II responds to the level transitions occurring during the switch time, but when this transition is sent to a buffer, it knows it is not data, so it ignores the change in potential between connections.

To use XON/XOFF with older software, it is necessary to use a pre-boot program to set up the Super Serial Card before using the software. On the Apple II GS, if you cannot gain access to the Control Panel from within the application, the pre-boot needs to be used there, too.

The pre-boot program should look like this in DOS 3.3 or ProDOS:

```
10 D$=CHR$(4)
20 PRINT D$;"PR#1"
30 PRINT CHR$(9);"X E";CHR$(13)
40 PRINT D$;"PR#0"
```

Enter this short program into the system in immediate mode prior to starting up the systems, or save it on disk as either a HELLO (DOS 3.3) or STARTUP (ProDOS) program to run before the software boots.

Bottom Line

-----

Change the ImageWriter II to XON/XOFF handshaking by setting SW 2-3 Open, and the problem of not being able to print from multiple systems should vanish. It is less convenient, but we have not been able to make the setup fail using this method.

## HyperCard: InBox 2.2 Incompatibilty

Revised: 12/4/89  
Security: Everyone

HyperCard: InBox 2.2 Incompatibilty

=====

This article last reviewed: 14 November 1989

TOPIC -----

This article discusses an incompatibility problem between HyperCard and InBox 2.2 under System Software 6.0.4.

DISCUSSION -----

A Macintosh running HyperCard 1.2.5 and System Software version 6.0.4 hangs when HyperCard is the active application in MultiFinder and the user receives an incoming InBox 2.2 memo, triggering Inbox's "audible warning".

The problem persists when the same configuration is used with HyperCard 1.2.2 under the same system software (v6.0.4), so it may be caused by the interaction of InBox and the system software.

Turning off the audible warning in InBox eliminates the problem, and is the only solution to the problem as of November of 1989.

## TokenTalk NB Card: How the Confidence Test Works

Revised: 12/4/89  
Security: Everyone

TokenTalk NB Card: How the Confidence Test Works

=====

This article last reviewed: 14 November 1989

TOPIC -----

After installing the SMB File Transfer software, I tried to run the TokenTalk NB Card Confidence Test. The card failed the test. (It passed the test before installing SMB.)

Following the failure, I was unable to access the AFE/SMB software. The message given was specific, and indicated that access to the Token Ring software was not available.

Restarting the Macintosh and accessing the AFE/SMB software resulted in immediate access to the SMB server (Normal operation).

I tried the confidence test again and it failed. Another attempt to access the AFE/SMB software was also unsuccessful.

It appears that there is an incompatibility between the SMB software and the confidence test -- or am I doing something wrong?

DISCUSSION -----

In our quick test, a TokenTalk NB Card also failed the Confidence Test when the test was launched from a hard disk. N&C QA provided us with the following information:

Such results may occur if the Confidence Test launching instructions are not strictly followed because of two inherent characteristics of the diagnostic:

- 1) The Confidence Test is destructive by nature; therefore, the Macintosh must be restarted after running the test.
- 2) The Confidence Test expects the TokenTalk NB Card to be in an idle state; therefore, the test must be run before the TokenTalk NB Card is

used. Any software using the TokenTalk NB Card will interfere with the Confidence Test and cause the test to indicate that the card is bad. (Once installed, Token Ring software may start using the TokenTalk NB Card at startup. So, if one runs the Confidence Test after starting up from a Token Ring software installed disk, the Confidence Test may indicate that the card is bad.)

The trick is to restart from a disk that has no Token Ring software installed, like the User Confidence Test disk, and to restart the Macintosh after running the test.

For more information, refer to the TokenTalk NB Confidence Test's initial dialog and the Apple TokenTalk NB User's Guide (page 18).

## Apple SCSI Drives: Why Hard Drive Access Time May Vary

Revised: 9/29/90  
Security: Everyone

Apple SCSI Drives: Why Hard Drive Access Time May Vary

=====

This article last reviewed: 14 November 1989

TOPIC -----

What is the "average access time" of internal HD40 SC drives, especially the HD40 SC found in a Macintosh SE/30?

DISCUSSION -----

The hard disk drive specifications that Apple supports are those published in our literature. The Macintosh Internal Hard Disk HD40 SC is rated with an average seek time of 30 milliseconds in literature dated February 1989. This doesn't necessarily mean that all drives will be that exact speed -- just that we claim they'll be at least that fast.

Our computers may ship with different hard drives during their product lifetimes. In the case of the Macintosh SE/30, customers may have received a Quantum, a Seagate, or a Sony. Each of these drives performs similarly, but mild differences are detectable using certain benchmark tests. The most noticeable difference in actual day-to-day operation would probably be the unique sounds made by each drive: the overall performance should not differ all that much.

Many factors influence which drive a customer receives with their Macintosh. When a drive manufacturer is unable to produce adequate quantities for us, we'll use another manufacturer. Sometimes drives are dropped from our approved hardware lists for one reason or another, and others are added. It is almost impossible to predict which drive a Macintosh will have.

The service situation is also difficult to predict. Our pool of service hard drives changes over time, much the same as our pool of new product drives does. All that is guaranteed is that our customers will receive replacement drives that are compatible, and that will match or exceed our published specifications.

## MacTCP: Ethernet And IEEE 802.3 Packets

Revised: 12/4/89  
Security: Everyone

MacTCP: Ethernet And IEEE 802.3 Packets

=====

This article last reviewed: 14 November 1989

TOPIC -----

To be useful in our environment, every IP implementation must use an "Ethernet-style data link layer (EtherType field)" type packet instead of the "IEEE 802.3/2 data link layer (Length field and SAPs)" type packet.

Which data link layer does MacTCP's IP use?

DISCUSSION -----

MacTCP, when using the Ethernet link level protocol as selected via the MacTCP CDEV, always uses Ethernet-style packets. We are not aware of any implementations of TCP/IP that use the IEEE 802.3 style packets.

When using the EtherTalk 2.0 link level protocol with MacTCP, IEEE 802.3-style packets are used. These packets have AppleTalk encapsulated in them, and they must be decapsulated by a DDP/IP gateway, such as a FastPath. These packets then are sent to the destination IP address in Ethernet-style packets.

(NOTE: The DDP/IP gateway needs to be AppleTalk Phase 2-compatible to work as described above.)

The only time IEEE 802.3-style packets are used is when using EtherTalk 2.0. These packets are seen only by other EtherTalk 2.0 nodes. EtherTalk 1.x uses the Ethernet-style packets.

CE QuickMail: Apple Tape Backup Incompatibility

=====

This article last reviewed: 14 November 1989

TOPIC -----

This article contains information about a QuickMail/Apple Tape Backup problem.

DISCUSSION -----

CE Software's QuickMail 2.0 server INIT causes the Apple Tape Backup software to freeze or crash the system when it is launched.

As of November of 1989, the only known workaround is to remove the QuickMail server INIT from the System Folder and restart the machine before attempting to back up the server.

## Macintosh Portable: Lead Acid Battery Alternative

Revised: 7/30/92  
Security: Everyone

Macintosh Portable: Lead Acid Battery Alternative

=====

Article Created: 14 November 1989  
Article Last Reviewed: 30 July 1992  
Article Last Updated:

TOPIC -----

If the lead acid battery of a Macintosh Portable is removed, and the 9-volt battery is replaced with an AC-to-9-volt adapter (plugged into the wall), can the machine still run? This would allow the user to make the Macintosh Portable a lighter, but transportable only, computer.

DISCUSSION -----

Apple recommends that the Macintosh Portable NOT be used without the internal lead acid battery. The battery is always in use even when the Apple Power Adapter is connected.

The Apple Power Adapter provides 7.5 volts DC at a nominal current of 1.5 amps, peak of 2 amps. This adapter will not adequately power the Portable without the lead acid battery installed.

It might be possible to use an AC/DC 9-volt adapter to power the system, thus eliminating the need for the lead acid battery, but the only gain from this would be the 3-pound reduction in the weight of the system.

Any weight savings obtained by removing the battery would be negated by the size and weight of a 9-volt adapter of the appropriate capacity, and not being able to use the machine without AC power available. These size, weight, and convenience factors seem to be the primary reasons for having a portable machine.

## TokenTalk NB Card: Using With MacTCP

Revised: 12/4/89  
Security: Everyone

TokenTalk NB Card: Using With MacTCP

=====

This article last reviewed: 14 November 1989

TOPIC -----

Can I use a TokenTalk NB Card with MacTCP? I would like to encapsulate IP packets in TokenTalk packets and route them through an AppleTalk Internet Router to a DDP-IP gateway, such as the GatorBox.

I know MacTCP is unable to use the TokenTalk NB Card directly, but I want to encapsulate IP in DDP and strip the AppleTalk off at the gateway.

If that is not possible, can I go from LocalTalk to the router to a Token Ring backbone to a router to LocalTalk to a DDP-IP gateway?

DISCUSSION -----

Yes, you can use the Apple TokenTalk NB Card with MacTCP if TokenTalk has been selected via the Network CDEV. (We have tested this configuration with a GatorBox but not with a FastPath 4.)

NOTE: It is important to remember that MacTCP 1.0 will not work across a router, including the AppleTalk Internet Router, if class C addressing is used. Class A and class B addressing, however, work properly.

Macintosh Keyboards: Enter Key Problems Are Key Code Difference

Article Created: 14 November 1989  
Article Last Reviewed: 15 July 1992  
Article Last Updated: 15 July 1992

TOPIC -----

I am experiencing a problem with the Macintosh Portable. It seems that the Enter key on my Macintosh Portable does not act like an Enter key on any of our other keyboards.

I am using terminal software that requires the Enter key. Under MacWrite II, the Enter key causes a page advance. Can you explain?

DISCUSSION -----

The ASCII code generated by the Enter key is \$03, which is consistent with all of Apple's keyboards that have Enter keys. The virtual key code, however, is not the same on all Apple keyboards. Here is a list of Macintosh keyboards and the virtual key codes their Enter keys return:

| Macintosh Keyboard                       | Virtual Key Code |
|------------------------------------------|------------------|
| -----                                    | -----            |
| Macintosh 128K, 512K Keyboard            | \$34             |
| Macintosh 128K, 512K Numeric Keypad      | \$4C             |
| Macintosh Plus Keyboard                  | \$4C             |
| Macintosh Standard Keyboard (ADB)        | \$4C             |
| Macintosh Extended Keyboard (ADB)        | \$4C             |
| Apple Keyboard II                        | \$4C             |
| Apple Extended Keyboard II               | \$4C             |
| Macintosh Portable Keyboard              | \$34             |
| Macintosh Portable Numeric Keypad        | \$4C             |
| Macintosh PowerBook 100 Keyboard         | \$34             |
| Macintosh PowerBook 140 and 170 Keyboard | \$34             |

The fact that the Enter key next to the Space bar on the Macintosh Portable returns a virtual key code of \$34 is most likely the reason the terminal software is having a problem.

These keys have different virtual key codes because it is possible to have two different Enter keys with these keyboards. The authors of the terminal software are not taking into account the possibility of a different virtual key code for the Enter key -- they are looking at the ASCII code of the key being pressed.

## Macintosh: Turning It Off Versus Leaving It On (8/94)

Revised: 8/1/94  
Security: Everyone

Macintosh: Turning It Off Versus Leaving It On (8/94)

Article Created: 12 April 1989  
Article Reviewed/Updated: 01 August 1994

TOPIC -----

I noticed that many of my fellow employees leave their Macintosh computers on overnight and on weekends. Is this good or bad? Is there a fire risk, or excessive energy waste?

DISCUSSION -----

These are controversial issues compounded by numerous variables.

The energy issue is left up to your conscience or company controller. However, it typically takes more energy to power up a system than may be consumed by leaving a system on. Read the Tech Info Library article, "Monitors Draw Extra Power at Startup."

As for fire risk, it is very low -- as mandated and enforced by various governmental agencies. Refer to the Tech Info Library article on "Certificate of Occupancy" for additional information on specific fire retardant materials, agency approvals, and so on, that our systems have. Service documentation explains the fuse protection that our systems contain.

Experts are strongly polarized as to whether power cycles are stresses beyond what the electronics were designed for, but there are other variables, including "sticktion", quality of power, and so on.

For instance, if you have personally encountered hard disk "sticktion" problems, you may have a strong opinion that hard disks should not be powered off. However, if you are in a region plagued by power outages or lightning-induced spikes or surges and so on, experience may have taught you that electronics should always remain off whenever they are not in use. A/UX users and AppleShare Administrators, of course, will also take into account the amount of time it takes to bring up their systems.

Knowing any particular idiosyncrasies of your system, weighted with any risks in your environment, should help you make the most intelligent decision.

In general though, if you are not going to use the system for 8 hours or more, powering it off is the wise choice.

King's Quest: Compatibility With GS/OS 5.0

=====

This article last reviewed: 14 November 1989

TOPIC -----

I have an Apple IIGS, and I would like to use King's Quest (from Sierra ON-LINE). Running under System 5.0 with only the icons of 5.0 and AppleWorks GS installed, I tried to install King's Quest and its icons, but the computer always hangs and I have to restart.

Without the Icons, the system performs OK. The same setup with all Icons worked fine on version 4.0 of the operating system. Can you explain?

DISCUSSION -----

There are a couple of things to watch when using some of the King's Quest programs:

- 1) If your version of King's Quest includes the program and icons, eliminate all of the King's Quest icons from your hard disk -- except for the program icon. Deleting these icons will not effect the functionality or performance of the program; these icons were used by the programmer when writing the program, and were not removed before the program disk was duplicated for distribution.
- 2) When using GS/OS 5.0, you must have 768K or more of memory (minimum used to be 512K). Alternatively, run the program from its program disk (which contains an older, less memory consuming version of the OS).

Good Luck King Graham, Gwydion, and Rosella!

Macintosh II Family: Why Color Icons Are Black and White

=====

Article Created: 14 November 1989  
Article Last Reviewed: 7 July 1992  
Article Last Updated: 7 July 1992

TOPIC -----

I would like to know why my color monitor with a 256-color video card displays a black Apple icon instead of a color icon for the DA menu. Also, why is the startup "Welcome to Macintosh" Macintosh icon not in color, although it is a color system?

DISCUSSION -----

The most likely cause is that your Monitors control panel is set to Black & White. If the Monitors control panel is set to Black & White, the Welcome to Macintosh icon and the Apple icon will be black. To get color icons, all you need to do is set the Monitors control panel to either 16 colors or 256 colors.

## Network Addressing Without Using A Router

Revised: 12/4/89  
Security: Everyone

Network Addressing Without Using A Router

=====

This article last reviewed: 14 November 1989

TOPIC -----

Is it possible for EtherTalk 2.0 or TokenTalk 2.0 to address more than 253 nodes without the benefit of a router? I understand that network numbers 65,280 to 65,534 are used only when a router is not present. If it is possible, how is network addressing accomplished?

DISCUSSION -----

Operation Without a Router

-----

If a node has a hint stored in parameter RAM, the node uses the AppleTalk Address Resolution Protocol (AARP) to determine if the address is still unique. If the address is unique, the node can begin communicating on the network. If the address is not unique, the node continues as if it had no hint.

When a node doesn't have a hint node address stored in parameter RAM, the node determines its address by first determining its network number, the first 16 bits of its node address. In the absence of a router, the node picks a network number from the startup range. This range is specified to be 65,280 to 65,534 (\$FF00 to \$FFFE).

A node then picks a node ID in the 0 to 253 (\$00 to \$FD) range. As in the past, a node ID of 0 is reserved to mean "send to myself", and 255 is reserved for broadcasts. With AppleTalk Phase 2, 254 is also reserved for internal use.

The node now has a node address in the form \$FFxxyy, where xx is the last part of the network number, and yy is the node ID. The node uses AARP to determine if any other nodes on the network are already using that node address. If no other nodes are using it, then the node adopts that as its node address. Otherwise, it tries a different node address.

## HDBackup: Problem and Solutions

Revised: 12/4/89  
Security: Everyone

HDBackup: Problem and Solutions

=====

This article last reviewed: 19 November 1989

TOPIC -----

HDBackup does not always ask for each disk when backing up or restoring a 1.9MB FileMaker II file. Do you have any suggestions?

DISCUSSION -----

We were unable to duplicate this problem.

We tested HDBackup 1.1 with System Software 6.0.2 on a Macintosh II, running MultiFinder and Finder. We were able to back up a variety of sizes of FileMaker files and 'other applications' files that ranged in size from a few K to a few that were so large they required more than one disk to hold them. We backed up using all of the options: all files, changed files, and a single file. We restored using both options: all and a single file.

There are some known problems, however, that can confuse users or jeopardize their data. You may be encountering one or more of these problems.

If you insert a disk containing your backed up information when just running the Finder or MultiFinder, you may never be able to restore from that disk again. Therefore, after backing up information onto disks using HDBackup, immediately write-protect them using the write-protect tab, and store them for use with only the HDBackup program.

If your disk is not recognized by HDBackup when you try to restore, you should be able to recover all of the information that isn't split over multiple disks (for example, you will be able to recover a 200K file but not one that is 1.5MB that is contained on multiple disks). Insert the disk while running the Finder or MultiFinder and merely copy the file.

(NOTE: This does not work with files that are split between two or more disks. Unfortunately, there are no tools or tricks to easily recover large files that

were backed up onto multiple disks.)

When running MultiFinder, if you attempt to restore all, you may immediately encounter the dialog, "That file already exists on the volume. Click continue to replace." Since the file in question is most likely the Desktop file, select OK. Another error message may display, "Tried to open a file to write to it twice -49." Typically, you can ignore this error message because it also refers to the Desktop file and click continue with no ill effects.

After restoring by file while running MultiFinder, close and open the folder or volume to which you restored the file. This alerts MultiFinder to update the new icons on the desktop. (These newly restored files' icons change from the generic document icon to the icon of that application, and Get Info displays the proper attributes of that file.) After which, you will be able to access the files normally.

If the problem you are encountering differs from the known problems described above, the directory structure may be damaged on the disk you are trying to back up, or the file itself may be damaged. Consider rebuilding the Desktop file on that volume and repairing it using a utility, such as Disk First Aid.

Because many of the problems described above are encountered only when using HDBackup under MultiFinder, it is best to run HDBackup under Finder.

## Macintosh Portable: Sound Volume Problem Solved

Revised: 7/27/92  
Security: Everyone

Macintosh Portable: Sound Volume Problem Solved

=====

Article Created: 19 November 1989  
Article Last Reviewed: 27 July 1992  
Article Last Updated:

TOPIC -----

I am having a problem controlling the volume on the internal speaker of our Macintosh Portable. Most of the time, the speaker is barely audible -- even though the volume control in both the General and Sound CDEVs is at 7.

I cleared PRAM by using the keyboard method (Control, Shift, Option, and Command). This procedure worked, but it raises a couple of questions:

- 1) What is causing the speaker volume to become so low?
- 2) Why does resetting the PRAM fix the problem, whereas removing the power supply via the battery removal/power-down sequence does not fix the problem?

DISCUSSION -----

- 1) The volume on your Macintosh Portable was low because the PRAM was getting scrambled.
- 2) To clear PRAM on the Macintosh Portable, both batteries must be removed for an undefined period of time -- probably more than 10 minutes. Otherwise, the 9-volt battery holds the values stored in PRAM. The easiest way to clear this memory is, as you discovered, by keyboard command.

## AppleTalk Internet Router 1.0 & 2.0: ADEV Files Question

Revised: 2/6/90  
Security: Everyone

AppleTalk Internet Router 1.0 & 2.0: ADEV Files Question

=====

This article last reviewed: 19 November 1989

TOPIC -----

After installing the AppleTalk Internet Router, the following problem occurred and was solved.

Situation  
-----

There are three separate LocalTalk-type networks, each going into a Star Controller (that is, three Star Controllers) -- Zone 1, Zone 2, and Zone 3. There is also an Ethernet backbone. Two Macintosh IIs are acting as routers between Zone 1 and Zone 2 and the Ethernet backbone and Zone 3 and the Ethernet backbone.

Macintosh II 5MB (#1)

- System Software Version 6.0.3
- EtherTalk 2.0
- AppleTalk Internet Router
- AppleShare 2.0.1
- AppleShare Print Server

Macintosh II 1MB (#2)

- System Software Version 6.0.3
- EtherTalk 2.0
- AppleTalk Internet Router
- AppleShare Print Server

#### Problem

-----

When configuring the router in the router setup for Macintosh II (#1), four ports appear: 1 Ethernet port, 1 LocalTalk modem port, and 2 LocalTalk built-in ports.

The appearance of this extra "LocalTalk built-in" port is impossible and doesn't make sense but, for some odd reason, continues to happen no matter how many times I restarted or tried to deactivate the port. The router actually runs in this configuration, but doesn't work properly.

Zone 1 is attached to the built-in port. However, whenever Zone 1 is chosen in the "Chooser" (after the router came on-line), none of the network services available in Zone 1 appear. Also, people in Zone 1 can't see any part of the network--including their zone (Zone 1). If I shut off the routers, everyone can see their respective zones including the Zone 1 people. Therefore, I know there is integrity in the physical media.

#### Solution

-----

Since the router setup on the Macintosh II (#2) was normal (that is, two total LocalTalk ports (modem/built-in) and one EtherTalk port), I assumed that there had to be something wrong with Macintosh II (#1). The only thing I was doing different on Macintosh II (#1) was running the AppleShare File Server.

After examining the System Folders for both Macintosh IIs (#1 and #2), I found two CDEVs that were installed by the AppleTalk Internet Router. "LocalTalk (Built-In)" and "LocalTalk (Modem)". Since I had two "LocalTalk (Built-In)" ports for my router setup on Macintosh II (#1), I decided to throw out the "LocalTalk (Built-In)" CDEV system document in the System Folder for Macintosh II (#1) and left it in Macintosh II (#2).

To my surprise, when I got into my router setup for Macintosh II (#1), everything was normal with one "LocalTalk (Built-In)", one "LocalTalk (Modem)", and one EtherTalk port. When I restarted both routers, the whole network started up, and everyone could see everything in the network -- including Zone 1.

#### Questions

-----

- 1) Why did this happen, and why did the solution work?
- 2) Why do you need a CDEV for "LocalTalk (Built-In)"? I thought that code was an integral part of the system (ROM or on some other chip).

- 3) If "LocalTalk (Built-In)" is not an integral part of the system, why haven't I ever seen a "LocalTalk (Built-In)" CDEV in the System Folder?
- 4) Does AppleShare File Server install some of its own resources that may cause conflicts with the AppleTalk Internet Router "LocalTalk (Built-In)" CDEV? This would explain why the Macintosh II (#2) didn't have any problems with the "LocalTalk (Built-In)" CDEV installed while Macintosh II (#1) did have problems.

#### DISCUSSION -----

- 1) The AppleTalk Internet Router 1.0 beta software (AppleTalk Phase 1 only) installs the files:

- Modem LocalTalk
- Printer LocalTalk

in the System Folder.

The AppleTalk Internet Router 2.0 installs the files:

- LocalTalk (Modem)
- LocalTalk (Printer)

in the System Folder. These four files are ADEVs, not CDEVs.

If the AppleTalk Internet Router 2.0 software was installed on a machine that had the AppleTalk Internet Router 1.0 beta software installed, you would have the "Printer LocalTalk" file from the AppleTalk Internet Router 1.0 beta software and the "LocalTalk (Modem)" and "LocalTalk (Printer)" files from the AppleTalk Internet Router 2.0 software in the System Folder.

The AppleTalk Internet Router 2.0 installer script removes the "Modem LocalTalk" file from the System Folder, but does not remove the "Printer LocalTalk" file. This is why the router setup window shows the two LocalTalk printer ports and the LocalTalk modem port.

The router did not work properly because both LocalTalk Printer port drivers were telling the printer port different things, which, in turn, caused the network problems. When you removed the "LocalTalk (Printer)" file, the AppleTalk Internet Router 2.0 software had only one driver talking to the printer port, and the problems stopped.

It is important to note that the "LocalTalk (Modem)" and "LocalTalk (Printer)" files from the AppleTalk Internet Router 2.0 software should be in the System Folder, and the "Printer LocalTalk" file from the AppleTalk Internet Router 1.0 beta software should be removed.

- 2 and 3) The AppleTalk Internet Router requires special LocalTalk drivers and uses RAM-based drivers instead of the ROM-based drivers. This is why you have not seen these files before.

- 4) The AppleShare File Server and AppleShare Print Server software does not conflict with the AppleTalk Internet Router software.

(NOTE: Apple Tech Comm recommends that the Macintosh II (#2) router have 2MB RAM installed, since it is running the AppleShare Print Server software in conjunction with the AppleTalk Internet Router.)

## AppleTalk: Node IDs, Node Hints

Revised: 12/4/89  
Security: Everyone

AppleTalk: Node IDs, Node Hints

=====

This article last reviewed: 19 November 1989

TOPIC -----

I have a large AppleTalk Internet. Using NodeHint by Farallon, I am able to assign node numbers to each workstation, allowing some control over the network. Is there a way to assign node IDs to AppleTalk printers, either by using the same method or another method?

DISCUSSION -----

The node hint is stored in the PRAM of the Macintosh computer. There is no method that we are aware of (as of November 1989) for assigning node hints for AppleTalk-based printers.

Also, using NodeHint to assign node numbers does not guarantee that the workstation will actually have node number assigned in PRAM. See the following for a detailed description of the node number assignment process:

Operation without a router

-----

If a node has a hint stored in parameter RAM, the node uses the AppleTalk Address Resolution Protocol (AARP) to determine if the address is still unique. If the address is unique, the node can begin communicating on the network. If the address is not unique, the node continues as if it had no hint.

When a node doesn't have a hint node address stored in parameter RAM, the node determines its address by first determining its network number, the first 16 bits of its node address. In the absence of a router, the node picks a network number from the startup range. This range is specified as 65,280 to 65,534 (\$FF00 to \$FFFE).

A node then picks a node ID in the 0 to 253 (\$00 to \$FD) range. As in the past, a node ID of 0 is reserved to mean "send to myself", and 255 is reserved for broadcasts. With AppleTalk Phase 2, 254 is also reserved for

internal use.

The node now has an node address in the form \$FFxxyy, where xx is the last part of the network number, and yy is the node ID. The node uses AARP to determine if any other nodes on the network are already using that node address. If no other nodes are using it, then the node adopts that as its node address. Otherwise, it tries a different node address.

#### Operation with a router

When a network administrator sets up a router, a network number range is specified for an extended AppleTalk network. The numbers in this range must be unique on the Internet. The network administrator also specifies a list of zone names that are valid for the extended network. As in the past, a router can depend on a seed router for the authoritative definition of network numbers and zone names.

When a router is present, an AppleTalk Phase 2 workstation node determines its node address in two steps. In the first step, the workstation establishes a potential temporary node address for communicating with a router. If the workstation has no hint to use, then it uses a number in the startup range and uses AARP until it finds a unique address.

If the workstation has been on an AppleTalk network previously, then it uses its hint node address and uses AARP to determine if that node address is still unique. If it isn't unique, then the workstation tries other node IDs with the same network number. If the workstation still can't find a unique address, it tries a network number in the startup range.

In the second step, a workstation uses its potentially temporary node address and proceeds to talk to the router to discover information about its environment. It learns from the router the range of valid network numbers for the cable and confirms that its saved zone name is valid for that cable.

If a node determines that its zone name is not valid, or it does not have a saved zone name, it can ask the router for the list of valid zone names and the name of the default zone. The software can allow the user to choose a zone name from the list of valid zone names. EtherTalk and TokenTalk software support this feature. Until the user goes into the Control Panel and chooses a zone, the node is in the default zone.

## Lisa Office System: Version 3.1 Still Calls Itself 3.0

Revised: 12/4/89  
Security: Everyone

Lisa Office System: Version 3.1 Still Calls Itself "3.0"

=====

This article last reviewed: 19 November 1989

TOPIC -----

I set up a Lisa with Lisa Office System version 3.1.

The Lisa Office System, however, although marked as version 3.1, appears as version 3.0 when it is installed. What's going on?

DISCUSSION -----

When Apple revised the Lisa Office System software to 3.1, we didn't change the dialog screens that appear when you install the software. Therefore, each disk shows version 3.0.

However, after installing the OS and starting up from the volume onto which you installed the software, check the startup "Wait" message box. This should properly reflect that the Lisa Office System you installed is in fact version 3.1 -- or, as it is commonly called, Lisa 7/7.

## MacWorks: Localization

Revised: 12/4/89  
Security: Everyone

MacWorks: Localization

=====

This article last reviewed: 19 November 1989

TOPIC -----

Is there a localized version of MacWorks (that is, the bottom two rows on the keyboard are transposed one place to the right, so "b" appears as an "n", and so on)?

DISCUSSION -----

No localized versions of MacWorks were created. Therefore, if you used localized Macintosh System Software, this version of the software assumes that the associated localized Macintosh 128/512K keyboard is being used.

Workarounds might include locating a QuicKeys or Tempo II-like program which is compatible with this older System Software, and which will let you remap the keyboard. Apple Tech Comm is not aware (as of November 1989) of such a program.

## HyperCard: General Problems with XCMDs and XFCNs

Revised: 6/24/90  
Security: Everyone

HyperCard: General Problems with XCMDs and XFCNs

=====

This article last reviewed: 24 August 1989

Using your own or someone else's XCMD or XFCN involves some risks. Some XCMDs may cause system crashes or unusual problems to appear. These problems usually result from not programming enough error protection into an XCMD and from lack of testing of the XCMD.

When running a new XCMD, first execute it within a test HyperCard stack. If a problem does occur within and corrupting the test stack, your real stack will not be damaged. Also, be sure to check the result of the XCMD or XFCN for any error messages. It's a good idea to put this statement into the script after executing the command:

"Put the result into the message"

Here are some possible XCMD or XFCN causes of system locks up:

- The memory management system is purging needed data of the XCMD or XFCN, because the XCMD or XFCN has not taken precautions to protect it.
- The XCMD or XFCN has broken the master-pointer block, and the problem is not uncovered until some random, future action.
- The memory manager's application stack has become fragmented causing an out-of-memory error, because the XCMD or XFCN has allocated memory, locked it down, and has not removed the data after it was finished.
- There just is not enough memory available.

There are several ways for XCMDs or XFCNs to crash. Almost all are due to lack of error checking and or defensive programming. Some are simply due to trying to use HyperCard in ways for which it was not designed. Anyone using an XCMD or XFCN needs to test the XCMD or XFCN in a stack by itself and slowly add and execute other XCMDs. Any one of the additions may fragment the memory manager's stack, corrupting the master pointer block, or using up memory by

leaving data floating around.

An XCMD or XFCN may not immediately cause problems. For example, a corrupted, master-pointer block may continue to work until a call is made to a once-valid pointer to your data. Once but is now corrupted the pointer points to garbage. The effect could be returning garbage to the stack, but usually, HyperCard chokes on the unexpected garbage data and crashes. Such a crash can take the system with it.

Apple does not support extensions that are not part of the HyperTalk language. The ability to add extensions was created, so that customers can enhance their stacks. However, each programmer must take the responsibility to check for errors and to report any problems to the user when writing the XCMD or XFCN. Be wary when faced with extensions from unknown sources.

Finally, a user's needs may not be appropriate for the capabilities of HyperCard. There are some supported XCMDs, like those available within legitimate HyperCard software products. We suggest HyperTalk programmers use only those XCMDs that they are confident with or that carry a guarantee for future support.

There are many other programming environments that support and handle advanced programming requirements. HyperTalk is not meant to be a replacement for programming languages like Pascal or C.

## MPW 3.0: Problem Using C Compiler

Revised: 12/4/89  
Security: Everyone

MPW 3.0: Problem Using C Compiler

=====

This article last reviewed: 25 October 1989

TOPIC -----

I think that there is a problem in "AppleTalk.h". It seems that the C compiler doesn't feel that the definition of the toolbox routine "BuildDDPwds()" is compatible with the definition of "AddrBlock". It seems like the actual toolbox routine is expecting the parameter to be passed by (a scalar) value, but the compiler is expecting a pointer.

I could not make one of our programs compile and work correctly until I changed the "AddrBlock" parameter to a type "long" in "AppleTalk.h" and passed the AddrBlock parameter in as a type "long" scalar parameter. Here is my change to "AppleTalk.h":

```
#if 0
pascal void BuildDDPwds(Ptr wdsPtr,Ptr headerPtr,Ptr dataPtr,const AddrBlock
*netAddr,short ddpType,short dataLen);
#else
pascal void BuildDDPwds(Ptr wdsPtr,Ptr headerPtr,Ptr dataPtr,long myAddrBlock,
short ddpType,short dataLen);
#endif
```

Any comments?

DISCUSSION -----

Although it seems at first that there is an error in the way this particular parameter is declared, the declaration actually makes sense when you look at the underlying mechanisms used by Macintosh Toolbox calls.

Because Macintosh Toolbox calls use Pascal parameter-passing conventions, an AddrBlock parameter is always passed as the address to that parameter. This happens because any parameter longer than 4 bytes automatically has its address passed to preserve stack space.

To mimic this calling convention, the C declaration for the BuildDDPwds declares the AddrBlock parameter as a pointer to an AddrBlock structure. When you call the BuildDDPwds routine, you are expected to pass a pointer to an AddrBlock structure you have declared.

For more information, see the Parameter types section of the "MPW C Reference."

## Apple Portrait Monitor: Macintosh SE/30 Card Availability

Revised: 10/22/90  
Security: Everyone

Apple Portrait Monitor: Macintosh SE/30 Card Availability

=====

This article last reviewed: 25 October 1989

TOPIC -----

I have a Macintosh SE/30 and want to use a full-page (not a two-page) monochrome monitor. Do you know of any monitors that work with the Macintosh SE/30?

DISCUSSION -----

Generation X Technologies has a line of 8-bit graphics cards for the Macintosh SE/30. The line includes the Vision '030X, a 1,024-by-768 resolution card with a 74 Hz vertical refresh rate. It will be available next month. The Vision '030A features 640-by-480 resolution and a refresh rate of 66 Hz. Both products include hardware pan and zoom, virtual desktop capability, and support for 1-, 2-, 4-, or 8-bit graphics.

Nutmeg Systems, Inc. offers also offers an SE/30 card for Apple's large monitors. Both the Apple Two-Page Monochrome Monitor and the Apple Macintosh Portrait Display can be driven by the new Nutmeg card, called the Nutmeg 30/2. The single card can drive either monitor due to the card's use of an auto-sensing circuit which detects which monitor is in use and then sends the appropriate signal to that monitor. If no external monitor is connected, the card lets the SE/30 monitor run by itself.

For more details, search the Tech Info Library under "Generation X" and "Nutmeg."

## EtherTalk 2.0: How It Reduces Broadcast Traffic (9/96)

Revised: 9/30/96  
Security: Everyone

EtherTalk 2.0: How It Reduces Broadcast Traffic (9/96)

=====

Article Created: 25 October 1989  
Article Reviewed/Updated: 30 September 1996

TOPIC -----

This article discusses how broadcast traffic is reduced when you use EtherTalk 2.0 instead of EtherTalk 1.0.

DISCUSSION -----

### Background

-----

In the past, versions 1.0 through 1.2 of Apple's EtherTalk software have caused excessive broadcast traffic when used on a large number of Macintoshes on an Ethernet network. Apple has fixed this problem with the EtherTalk 2.0 version of the software by using multicast addressing.

### Ethernet Broadcast Traffic

-----

All nodes on an Ethernet local area network listen to broadcast packets that are addressed to the general-purpose broadcast address FF-FF-FF-FF-FF-FF. EtherTalk 1.0 used this address for all AppleTalk name lookups, Routing Table Maintenance Protocol traffic between routers, and other types of AppleTalk broadcast packets. Large sites like universities and research labs found this to be a problem, because all of their non-Apple hardware had to accept Apple's packets, read them, then discard them. This translated into lost machine cycles on VAXs, Suns, and so on. In some extreme cases, Sun diskless workstations can crash if they're booting and take a broadcast packet at the wrong time.

### Ethernet Multicast Addressing

-----

Ethernet addresses actually have two parts. The first 24 bits (written as xx-xx-xx) are a vendor code. Apple's codes are 08-00-07, 00:05:02, and 00:A0:40. The second 24 bits designate a unique machine with that vendor code. If a certain bit in the first byte of the vendor code is turned on, the address is said to be a "multicast address" and ALL Ethernet interface boards with that

vendor code will receive the packet. (Apple's multicast vendor code is 09-00-07).

An Ethernet interface board can be programmed to accept only packets with certain multicast addresses. These are the only packets which are passed to the higher level protocols; the hardware rejects all others. This results in a significant efficiency, because it means that the Ethernet interface board will only interrupt the main CPU when "useful" packets are received.

#### EtherTalk 2.0

-----  
EtherTalk 2.0 no longer sends all AppleTalk broadcasts to the general-purpose Ethernet broadcast address. When EtherTalk 2.0 needs to send a packet to all EtherTalk 2.0 nodes, it sends to the multicast address 09-00-07-FF-FF-FF. All EtherTalk 2.0 nodes are registered to receive these packets.

In addition, EtherTalk 2.0 uses a range of other multicast addresses for its Name Binding Protocol (NBP) lookups. This range includes 09-00-07-00-00-00 through 09-00-07-00-00-FC. If there is a service (like a print spooler, or even Responder) registered on a Macintosh, the Macintosh will listen to NBP packets addressed to an address in the NBP multicast range. The Macintosh's zone name determines which address the Macintosh listens to. For example, if a file server is in zone "foo", it might expect file server client software to send lookup requests to the multicast address 09-00-07-00-00-27.

The Ethernet hardware does not pass lookups for a different zone (different multicast address) onto the EtherTalk software. A file server in a different zone would receive lookup requests to a different multicast address.

(Actually, there isn't an exact one-to-one mapping between zone names and multicast addresses. The Zone Information Protocol on routers assigns multicast addresses to zones, but because of the hash function used, there may sometimes be more than one zone assigned to one multicast address, but this is not likely.)

The important thing to understand is that in almost all cases, nodes are no longer disturbed by broadcast traffic that has no relevance to them. This leaves the CPU available for more important tasks.

#### Improvements for Multi-Vendor Environments

-----  
As discussed above, multicast addressing reduces the amount of processing that Macintoshes need to do because NBP lookups are sent to multicast addresses instead of to the general-purpose Ethernet address. However, the biggest improvement that EtherTalk 2.0 offers is that non-AppleTalk nodes are no longer disturbed by general-purpose Ethernet broadcasts generated by AppleTalk devices. When Macintoshes only run EtherTalk 2.0, they no longer send general-purpose Ethernet broadcasts.

Non-AppleTalk nodes, (i.e. Suns, VAXs, and so on) do not register to receive packets sent to Apple's multicast address 09-00-07-FF-FF-FF or Apple's NBP range of multicast addresses, 09-00-07-00-00-00 through 09-00-07-00-00-FC. Non-AppleTalk nodes no longer need to spend machine cycles reading

Apple-specific Ethernet broadcasts only to learn that they didn't need to. Many large customers, especially university, government, and Fortune 500 business accounts have become more amenable to placing Macintoshes on their Ethernet networks.

NOTE: TokenTalk 2.0 also uses multicast addressing. The concept is the same: non-AppleTalk nodes on the Token Ring will not be disturbed by Apple-specific broadcasts. The exact implementation of Token-Ring, multicast addressing is different than the Ethernet implementation.

## RGB-to-NTSC Video Converter

Revised: 12/4/89  
Security: Everyone

RGB-to-NTSC Video Converter

=====

This article last reviewed: 11 October 1989

TOPIC -----

I am looking for a RGB-to-NTSC video converter that works well with ChunkTV.  
Any suggestions?

DISCUSSION -----

MARKERTEK Video Supply makes a RGB-to-NTSC video converter, model number  
RN-1. The 1989 catalog description reads:

RGB Plus sync input to NTSC video out. This card will only be  
effective if the horizontal scan rate of the input is close to  
the standard NTSC video horizontal sync frequency of approximately  
15.75 KHz. (This is what ChunkTV does.)

You still have to make a special cable for the Macintosh II extended video  
card--nothing terribly difficult, though.

## NRC Series 2000 AppleTalk Routers: Description

Revised: 12/4/89  
Security: Everyone

NRC Series 2000 AppleTalk Routers: Description

=====

This article last reviewed: 2 November 1989

TOPIC -----

This article describes Network Resources Corporation's (NRC) Series 2000 family of AppleTalk routers.

DISCUSSION -----

The NRC Series 2000 family of AppleTalk routers are designed for Ethernet, broadband, and fiber-optic backbone media. These products can directly connect Macintoshes, AppleShare servers, and LaserWriters to a backbone. They can also connect a LocalTalk or PhoneNet subnet of Macintoshes, AppleShare servers, and LaserWriters to the same backbone.

The Series 2000 products have an architecture that reduces network overhead and extends network capacity. The following is a list of the features common to all Series 2000 products:

- Full EtherTalk compatibility, ensuring inter-operability with other non-NRC EtherTalk devices (like Kinetics, Apple Ethernet adapters, and so on). This is typically an issue in existing Ethernet user locations.
- Works well with large networks, because it can handle over 10,000 routing table entries.
- Self-configuring by default. Network administrators are not required to assign network ID and the like prior to placing the units into service. Self-configuration greatly reduces complexity and the possibility for error when putting the Series 2000 units into service. The units remain manually configurable, for networks with special needs.
- Minimizes activity on the backbone network improving overall network performance. The Series 2000 routers issue far fewer routing table broadcast and use a smaller size broadcast packet than existing non-NRC

solutions.

- Standard AppleTalk protocol support. This ensures compatibility with products like Inter-Poll.

- AppleTalk Phase II compatible.

The following is a list of the Series 2000 products currently offered:

AT2000 supports a single AppleTalk connection via a standard Apple Peripheral-8 cable, connected to the AppleTalk port of an AppleTalk device.

AT2002 supports two AppleTalk connections via standard Apple Peripheral-8 cables, connected to the AppleTalk ports of any two AppleTalk compatible devices.

LT2000 supports a LocalTalk or PhoneNet subnet, including one or more StarControllers in the PhoneNet configuration.

Mac2000 is an Apple Coprocessor Platform (MCP) NuBus adapter card. The Mac2000 is an intelligent device that processes the protocols on the board for higher throughput. The Mac2000 is best applied to server applications which require direct connection to the high-speed backbone.

#### Specific Media Applications

-----  
The Series 2000 supports three media applications:

- Ethernet cable
- Broadband CATV cable
- Fiber optic cable

Ethernet cable: The Series 2000 Ethernet options support both AUI (thick yellow cable) or Cheapernet (thin coax) connections. All standard Ethernet media support is standard.

Broadband CATV cable: The broadband offering of the Series 2000 makes use of standard broadband CATV cable for the high-speed backbone. Broadband's popularity has grown over the years due to it's ability to cover vast distances with both video and data transmission. Broadband data networks have been particularly popular in universities, manufacturing environments, corporate campus systems, and municipalities. In the latter case, some cities use the community CATV cable system to transport data traffic along with entertainment TV. Series 2000 devices use a 2 Mbps broadband modem to connect to the cable system and one of many 6Mhz TV channels to route AppleTalk packets up to 10 miles across the broadband system.

Fiber optic cable: The Series 2000 supports Fiber Optic high-speed backbones using a hub and star topology. The Series 2000 employs an active 16 port hub which supports either 62.5 micro fiber up to 3000-foot from the

hub or 1000 micro plastic fiber for distances up to 250-foot from the hub.  
The hubs can be tiered so you can daisy chain up to 16 hubs.

## Inside AppleTalk: Network Questions & Answers (11/95)

Revised: 11/21/95  
Security: Everyone

"Inside AppleTalk": Network Questions & Answers (11/95)

=====

Article Created: 4 December 1989  
Article Reviewed/Updated: 21 November 1995

TOPIC -----

This article contains a series of questions based on material in "Inside AppleTalk" with answers. References to "Inside AppleTalk" are from the March 1989 edition (ISBN 0-201-19257-8), published by Addison-Wesley.

DISCUSSION -----

What's a Protocol Stack

-----

Question: "Inside AppleTalk" suggests that a protocol stack is an implementation of a protocol suite, like AppleTalk for VMS or AppleShare PC. Most other literature refers to a protocol stack as a subset of the OSI model. An example is TCP, which does not include layers 6 and 7 or selected protocols with AppleTalk. Which is more accurate? The implementation idea or the subset idea?

Answer: Protocol stacks often implement only a portion of the OSI 7-layer model. A protocol stack is a suite of protocols that implements the feature set for a particular networking scheme. The term "protocol stack" typically refers to the actual implementation of a networking scheme. TCP/IP's protocol stack only implements the layers that it needs, whereas AppleTalk implements all of the layers.

The OSI Model and Protocols

-----

Question: Often, I have heard (and saw documented in "Inside AppleTalk") that the OSI model is a general description of protocol usage and not the protocols themselves. Yet page I-22 of "Inside AppleTalk" cautions that AppleTalk is not necessarily compatible with the forthcoming OSI protocols.

What are these forthcoming protocols? What is OSI, if not a reference to follow for integration into heterogeneous networks? What protocols for OSI

have already been established? Are these based on CCITT protocols like X.25 and X.400? (It seems to me that although we have protocols that match every layer of OSI, we are only loosely tied to those layers. Is this so?)

Answer: The OSI 7-layer model has become a standard in the industry for describing network architectures. This model was originally designed as a blueprint for the OSI network protocols that were and still are in the process of being implemented. Many of the lower layers have already been implemented, and there are even products available for the Macintosh that provide connectivity solutions to these protocols. The press has often described the OSI architecture as the replacement for TCP/IP.

Although we have a network architecture that fits nicely within the OSI model, AppleTalk cannot be considered an implementation of OSI any more than it can be considered an implementation of TCP/IP. We use the model, because it provides a concise and elegant way to describe our network. We do not use the OSI architecture, because many of its layers remain undefined.

AFP an Application?

-----  
Question: "Inside AppleTalk" shows AFP to be mostly Presentation and part Application.

What aspects of AFP are Application? Wouldn't AppleShare File Server and AppleShare Workstation be applications?

Answer: We are not sure why AFP is listed as falling partially into the application layer. We assume that it has to do with the fact that the description of AFP in later chapters includes actual network services. AFP does define many of the features that need to be implemented in AFP servers. If this is the reason AFP falls partially in this layer, then AppleShare implements the highest part of the application layer, putting the interface on the services that have, at least, been partially defined by AFP.

CMSA/CA

-----  
Question: I understand that CSMA has at least two flavors: 1-persistent and non-persistent. 1-persistent is when a deferring sender grabs the channel as soon as it's released, contending with another sender who grabs the channel at the same time. Non-persistent throws in a random period of time to back off before attempting to grab the channel. Is this what we call CSMA/CA? Or, is CA something different? Or, is it non-persistent including handshaking? (See page 1-3, "Inside AppleTalk.")

Answer: The CA in CSMA/CA stands for "Collision Avoidance". It does implement the random period of time you mentioned as opposed to collision detection (CD).

Ethernet throughput

-----  
Question: They say that the 10MBps of Ethernet is only used under heavy loads and that its throughput does not come through at that rate. What does this mean? Are nodes communicating at 10MBps or not? Is Ethernet a broadband network? How

are the channels within the broadband used? (You can refer me to some other documentation on that last one.)

Answer: "Throughput" is a term used to describe the actual rate of transfer achievable over a network. This is a relative term, similar in reliability to "MIPS" or "megaflops." Network throughput is often measured by copying large files across a network and calculating the amount of data transferred in a specified period. As you can see, this throughput depends on the overhead of the protocols being used and the capability of the servers to transmit data to the client. The 10MBps specified for Ethernet refers to the ideal maximum possible over coaxial cable and is never achieved in real-world situations.

Standard Ethernet coax is baseband cable, not broadband. However, these days, you can run Ethernet over many different media, including broadband cable, unshielded twisted-pair telephone wiring, T1 telephone circuits, satellite links, and leased lines. These have different speeds and characteristics.

Bridge

-----  
Question: A bridge is a datalink layer device only. It separates networks but does not use network numbers. Right?

Answer: A bridge is used to connect two physical networks of the same type into one logical network. As far as any node on the network is concerned, this is a single network.

Router

-----  
Question: A router is a higher-level device (either transport or network layer) that routes like-protocols from one network to another. The networks on either side are identified by their network numbers. Like-protocol routing includes AppleTalk-to-AppleTalk, TCP/IP-to-TCP/IP, SNA-to-SNA, and so on. Right?

A: A router is used to divide two physical networks into separate logical networks using the same protocols. Each logical network has its own unique network identifier(s) distinguishing that network from other networks on the same Internet.

Networks and Bridges

-----  
Question: AppleTalk is a network protocol suite. A network is a specified physical cable and datalink, like Ethernet and Token Ring. A physical network is a cable. Are these accurate? Does a bridge create an Internet? Are the segments on either side of the bridge networks or just physical networks? Are physical networks and segments synonymous?

Answer: The physical network, or layer, typically refers to the physical medium in use. This can be cable, twisted-pair wiring, and so on. If you go with the definition above, a bridge does not create an Internet. A router provides the necessary functionality and acts at a high-enough level to create an Internet.

A "segment," as you are using it, is a piece of cable or set of wiring that is part of a physical network. This usually means as the physical medium on one side of a bridge or router, but it could be a smaller part.

## A/UX: How To Use Prototyper as Development Tool

Revised: 9/16/92  
Security: Everyone

A/UX: How To Use Prototyper as Development Tool

=====

Article Created: 12 April 1989

### Article Change History

-----

08/31/92 - REVIEWED

•For technical accuracy.

### TOPIC -----

These notes explain how to use Prototyper 2.0 as a development platform for A/UX.

### DISCUSSION -----

#### Introduction

-----

Prototyper 2.0 is a screen layout and code generator that produces most of the code and resources necessary for the Macintosh user interface part of the program. Prototyper release 2 includes things like MPW C 3.0 code generation, pop-up and hierarchical menus, and linking icons and menu entries to various other windows and dialog boxes. We hope these notes help people get up to speed when using Prototyper as a development tool for A/UX programs that make use of the Toolbox.

As stated above, Prototyper is a very versatile tool. A programmer saves a lot of time and energy when using Prototyper for the base program. The use of prototyping tools and object-oriented methodologies speeds up the boring parts of the programming job.

In general, one can define a simple interface and produce code within 10 minutes. Depending on the level of complexity, the design phase takes much longer.

#### How To Use Prototyper

-----

Prototyper runs well under A/UX. There are some things that make the program bomb, but, in general, the program is quite stable. When you design anything with Prototyper, you start with the user interface. This phase usually takes much longer than anticipated.

Prototyper saves this frozen user interface in a special file. You are able to cold-run this interface during the prototyping phase as much as you want. This is especially helpful because it saves time compared with endless testing-recompilation phases and sleepless nights.

You can produce either resource code (in .RSRC and .R format, .R stands for the old RMaker program), or both resource and code. In our case, we will choose MPW 3.0 code because this best reflects the A/UX environment.

The only worry when Prototyper produces source and resource code is that the tab settings are a bit unusual for the A/UX environment. This is easy to change with some clever sed programming. Another thing to think about is the 14-character limit of filenames. Prototyper tries happily to produce filenames that reflect the names of windows and dialogs used inside the code, and many times the names are longer than 14 characters. You can define your own names when Prototyper produces the C source code files.

Remember to strip out the AppleSingle/Double stuff from the top of the file before you continue in the A/UX file system with UNIX tools.

#### Resources

-----

The .RSRC format can be translated back to the rez/derez format that rez/derez uses within A/UX. The following shell script does the job handily:

```
if [ -f ${1}.res ] then
    echo Output file \(${1}.res\) exists!
    echo No action taken
    exit
fi
echo Doing derez of file $1.RSRC - new resource file will be $1.res derez
-i/usr/lib/mac/rincludes ${1}.RSRC types.r > ${1}.res
```

What you then need to do with the produced .res file is to include a statement type:

```
#include "types.r"
```

at the top of the file for the ultimate rez of the resource file. This is for the make, so it will find the resource type templates in the A/UX system.

Prototyper makes a special OpenResFile call inside the produced C code that opens a special resource file. Comment this because we will use the AppleDouble style resource files.

#### C Code

-----

The C code produced by Prototyper is very ANSI-C-oriented. Thus, some parts of

the code have to be changed so it will compile under A/UX. The most annoying things to change are the so-called function prototypes, usually found in the .h files.

For instance, if Prototyper produces function declarations like:

```
void Foo(WindowPtr MyWindow, ControlHandle CItem);
```

we have to change this to:

```
void Foo()
```

in the .h files, and sometimes in the .c files. Note that these are function declarations, and not the actual function headers. For me, it is annoying because the function prototypes help a lot when you have written code that wants to call a function with the totally incorrect data type. ANSI C function prototypes complain about it during the compilation; normal K&C compilers like pcc happily accept the variables.

Another issue is the string used in MPW and A/UX. In MPW, you can declare Pascal strings with the handy \p in front of the string, as in:

```
DrawString("\pThis is a Pascal String");
```

This won't work with A/UX, so you have to use the small letter Toolbox calls that know about C strings, like:

```
drawstring("This is my String");
```

The best thing is to define:

```
#define DrawString drawstring
```

in a special header file. This is also true with string functions, such as GetIText and SetIText.

Another thing to change are the filenames for the Toolbox modules. They usually have capital letters in their names, so you need to change names such as QuickDraw.h to quickdraw.h.

Note that all this could be done with #ifdef statements in the code; that is, you could use the same base for both Macintosh OS and A/UX code.

In general, the code produced is stable, but not much is optimized. It also leaves dangling handles that you need to keep track of and remove if you want to have really bug-free code.

Prototyper produces code with comments, so it is very easy to dive into the code and change or modify things. Still, you need to know the fundamentals of Macintosh programming if you want to change or enhance the C code.

Don't forget to use select(2) to poll for interrupts on the Macintosh Toolbox device; otherwise, you spend too many resources for the Macintosh program

itself. For more details, read the term sources.

#### Makefile

-----

The easiest way is to copy the example one found under /usr/lib/mac/examples and tweak this to reflect the source files.

#### End Result

-----

Well, after about 10 minutes and with a clever idea, you have a working base program and can continue with the rest of the UNIX programming. After a while, you realize that with Prototyper the user interface is 80% of the job, and the function coding is a small portion of the creative work. I would highly recommend this product if you want to write A/UX tools and applications that make use of the Macintosh side of A/UX.

If you are unsure (as I am) about scroll bars in windows, check the latest code examples from Phil and Dave's Excellent CD. There is a really good example that works under A/UX, as well.

## Screen-Dump II: Description

Revised: 12/4/89  
Security: Everyone

Screen-Dump II: Description

=====

This article last reviewed: 2 November 1989

TOPIC -----

This article discusses a shareware program named Screen-Dump II.

DISCUSSION -----

Screen-Dump II is an FKEY to replace the old Apple FKEYs 3 and 4. Screen-Dump II works on all Macintoshes and adjusts to all screen sizes. Included are three FKEYs, two to dump to black and white (whether or not you are using color). The other one is for dumping to PixelPaint, GIFF, GrayView, or StartUpScreen format in full 256 colors.

Macintosh: Determining Video Card Status via Software (1 of 2)

=====

Article Created: 2 November 1989  
Article Last Reviewed: 14 July 1992  
Article Last Updated:

TOPIC -----

How can an application detect information about the status of the video display system connected to a Macintosh? For example, how many bits per pixel are selected via the Monitors cdev, and how many bits per pixel is supported by the card in the system? Inside Macintosh Volume V mentions using some high-level Color QuickDraw call. How is this implemented?

DISCUSSION -----

Refer to the QuickDraw chapters of "Inside Macintosh, Volume V." Page 124 documents a function called "GetMainDevice". This function returns a GDHandle (Graphics Device Handle). This handle has the information you want. Here is its description (page 119):

TYPE

```
GDHandle = ^GDPtr;
GDPtr    = ^GDevice;
GDevice  = RECORD
    gdRefNum:    INTEGER;
    gdID:        INTEGER;
    gdType:      INTEGER;
    gdITable:    ITabHandle;
    gdResPref:   INTEGER;
    gdSearchProc: SProcHndl;
    gdCompProc:  CProcHndl;
    gdFlags:     INTEGER;
    gdPMap:      PixMapHandle;
    gdRefCon:    LONGINT;
    gdNextGD:    GDHandle;
    gdRect:      Rect;
```

```
gdMode:      LONGINT;  
gdCCBytes:   INTEGER;  
gdCCDepth:   INTEGER;  
gdCCXData:   Handle;  
gdCCXMask:   Handle;  
gdReserved:  LONGINT;  
END;
```

The field in the above Pascal record with is the "gdPMap" field. The "gdPMap" field contains a PixMapHandle. Here is a description of the handle (pages 52 and 53):

```
TYPE  
  PixMapHandle = ^PixMapPtr;  
  PixMapPtr    = ^PixMap;  
  PixMap       = RECORD  
    baseAddr:  Ptr;  
    rowBytes:  INTEGER;  
    bounds:    Rect;  
    pmVersion: INTEGER;  
    packType:  INTEGER;  
    packSize:  LONGINT;  
    hRes:      Fixed;  
    vRes:      Fixed;  
    pixelType: INTEGER;  
    pixelSize: INTEGER;  
    cmpCount:  INTEGER;  
    cmpSize:   INTEGER;  
    planeBytes: LONGINT;  
    pmTable:   CTabHandle;  
    pmReserved: LONGINT;  
  END;
```

This "PixMap" record has a field called "pixelSize" that contains the current depth, in bits, of the pixels for the graphic device.

The Pascal code to retrieve this information looks something like this:

```
PROCEDURE GetBitsPerPixel;  
  
  VAR  
    mainDevice: GDHandle;  
    theDepth:  INTEGER;  
  
  BEGIN  
    mainDevice := GetMainDevice;  
    theDepth := mainDevice^.gdPMap^.pixelSize;  
  END;
```

If more than one video card is installed in the system, and you need to know what the bits per pixel setting is on all devices, not just on the main device, try the following functions (page 124):

```
GetDeviceList  
GetNextDevice
```

Here is a sample procedure that shows how to use them:

```
PROCEDURE GetGraphicDevs;  
  
  VAR  
    DeviceList: ARRAY[1..6] OF GDHandle;  
    theDepthList: ARRAY[1..6] OF INTEGER;  
    x: INTEGER;  
  
  BEGIN  
    DeviceList[1] := GetDeviceList;  
    theDepthList[1] := DeviceList[1]^^.gdPMap^^.pixelSize;  
    FOR x := 2 TO 6 DO  
      BEGIN  
        DeviceList[x] := GetNextDevice(DeviceList[x - 1]);  
        IF DeviceList[x] <> NIL THEN  
          theDepthList[x] := DeviceList[x]^^.gdPMap^^.pixelSize  
        ELSE  
          x := 6;  
        END;  
      END;  
    END;
```

If you need to find which device in the device list array created above is the main device, use the "TestDeviceAttribute" function described on page 124. Here is a code fragment showing how to use the function:

```
IF TestDeviceAttribute(DeviceList[1], mainScreen) THEN...
```

If the "TestDeviceAttribute" function returned "TRUE" or "1" in the example above, then "DeviceList[1]" is the main screen. If the function returned "FALSE" or "0", then the device is not the main screen. You can also use this function to determine if the device is in color model. For example:

```
IF TestDeviceAttribute(DeviceList[1], gdDevType) THEN...
```

If the "TestDeviceAttribute" function in this example returned "TRUE" or "1", then "DeviceList[1]" is in color mode; if it returned "FALSE" or "0", then it is in monochrome mode.

## Apple Internet Router: Memory Bank Manager Compatibility

Revised: 2/6/90  
Security: Everyone

Apple Internet Router: "Memory Bank Manager" Compatibility

=====

This article last reviewed: 11 October 1989

TOPIC -----

Can I run the Apple Internet Router along with a tape backup program from Northern Telecom called "Memory Bank Manager"?.

DISCUSSION -----

As of July, 1989, we have not tested Northern Telecom's "Memory Bank Manager" software (an AppleShare foreground application) and cannot make any statements on whether or not it works properly with AppleShare and the AppleTalk Internet Router. We do recommend that 2MB RAM be used in this situation.

On an AppleShare File Server, the AppleTalk Internet Router runs in the background; it does not run as a foreground application. Because the Internet Router runs in the background, you can run an AppleShare foreground application on the same machine.

## AppleShare File Server: Process Limits

Revised: 2/6/90  
Security: Everyone

AppleShare File Server: Process Limits

=====

This article last reviewed: 11 October 1989

TOPIC -----

What is the official answer as to how many processes can be run on an AppleShare File Server?

DISCUSSION -----

There is no "official" answer that describes how many processes can be run on an AppleShare File Server at one time. The AppleTalk Internet Router is the only product that we have tested on an AppleShare File Server that is running a foreground application (AppleShare Print Server). Based on this information, three processes is the maximum that we have tested and support.

On an AppleShare File Server, the AppleTalk Internet Router runs in the background; it does not run as a foreground application. Because the Internet Router runs in the background, you can run an AppleShare foreground application on the same machine.

Macintosh: No Restriction on System Folder Location

=====

This article last reviewed: 11 October 1989

TOPIC -----

Is there anything wrong with having the System Folder located within another folder on the Macintosh desktop?

DISCUSSION -----

The System Folder can be located on the Desktop, the root level, or anywhere in the volume hierarchy. There is no restriction on where the System Folder can be located. We suggest locating the System Folder at the root level of the volume, because the folder is accessed so often.

## LaserWriter IISC: Quotation Marks, Printed versus On-Screen

Revised: 12/4/89  
Security: Everyone

LaserWriter IISC: Quotation Marks, Printed versus On-Screen

=====

This article last reviewed: 20 September 1989

TOPIC-----

What is the difference between the way characters appear on my Macintosh screen and on the LaserWriter? In particular, how are the different types of quotation marks produced?

DISCUSSION-----

When the Macintosh displays characters on the screen, it uses the information from the font resource to show the character the best way it can, given that the Macintosh screen is 72 dpi. Likewise, when the driver prints the document to the LaserWriter IISC, it also uses the information from the font resource (rather than the bitmapped display) to create the printed output in its 300 dpi format. The printer always prints a more accurate representation of the actual font than the screen.

Also, be sure you are pressing Option-[ and Option-Shift-[ for open and close double quote marks instead of the quote key. Likewise, Option-] and Option-Shift-] produce open and close single quote marks. In the case of Times, the quote key and Option-Shift-[ produce the same results, but this is not true of all fonts (Helvetica, for example).

## Apple Internet Router 2.0: Multicast Addressing Description

Revised: 2/6/90  
Security: Everyone

Apple Internet Router 2.0: Multicast Addressing Description

=====

This article last reviewed: 2 October 1989

TOPIC-----

I am investigating the possibility using my corporate Ethernet backbone to link AppleTalk networks. I need background information on Apple's Internet Router 2.0 and whether it uses broadcast or multicast addressing for its RTMP traffic on the backbone.

DISCUSSION-----

Apple's Internet Router uses multicast addressing for its RTMP updates, sent out every 10 seconds. A more in-depth explanation follows:

Background

-----

In the past, the versions 1.0 through 1.2 of Apple's EtherTalk software have caused excessive broadcast traffic when used on a large number of Macintoshes on an Ethernet network. Apple has fixed this problem with EtherTalk 2.0 by using multicast addressing.

Ethernet Broadcast Traffic

-----

All nodes on an Ethernet local area network listen to broadcast packets that are addressed to the general-purpose broadcast address FF-FF-FF-FF-FF-FF. EtherTalk 1.0 used this address for all AppleTalk name lookups, Routing Table Maintenance Protocol (RTMP) traffic between routers, and other types of AppleTalk broadcast packets. Large sites, like universities and research labs, found this to be a problem, because all of their non-Apple hardware had to accept Apple's packets, read them, and then discard them. This translated into lost cycles on VAXs, Suns, and so on. In fact, in some extreme cases, Sun diskless workstations crash, if they're booting and take a broadcast packet at the wrong time.

Ethernet Multicast Addressing

-----  
Ethernet addresses actually have two parts. The first 24 bits (written as xx-xx-xx) are a vendor code. Apple's code is 08-00-07. The second 24 bits designate a unique machine with that vendor code. If a certain bit in the first byte of the vendor code is turned on, the address is said to be a "multicast address" and ALL Ethernet interface boards with that vendor code receive the packet. (Apple's multicast vendor code is 09-00-07).

An Ethernet interface board can be programmed to accept only packets with certain multicast addresses. These are the only packets that are passed to the higher-level protocols; all others are rejected by the hardware. This results in significant efficiency, because the Ethernet interface board interrupts the main CPU only when "useful" packets are received.

#### EtherTalk 2.0

-----  
EtherTalk 2.0 no longer sends all AppleTalk broadcasts to the general-purpose Ethernet broadcast address. When EtherTalk 2.0 needs to send a packet to all EtherTalk 2.0 nodes, it sends to the multicast address 09-00-07-FF-FF-FF. All EtherTalk 2.0 nodes are registered to receive these packets.

In addition, EtherTalk 2.0 uses a range of other multicast addresses for its Name Binding Protocol (NBP) lookups. This range includes 09-00-07-00-00-00 through 09-00-07-00-00-FC. If there is a service (like a print spooler or even a Responder) registered on a Macintosh, the Macintosh listens to NBP packets addressed to an address in the NBP multicast range. Which address the Macintosh listens to is a function of the Macintosh zone name. For example, if a file server is in zone "foo", it might expect file server client software to send lookup requests to the multicast address 09-00-07-00-00-27.

The Ethernet hardware does not pass lookups for a different zone (different multicast address) onto the EtherTalk software. A file server in a different zone would receive lookup requests to a different multicast address.

(Actually, there isn't an exact one-to-one mapping between zone names and multicast addresses. The Zone Information Protocol on routers assigns multicast addresses to zones. However, because of the hash function used, there may be more than one zone assigned to one multicast address, but this is not likely.)

The important thing to understand is that in almost all cases, nodes are no longer disturbed by broadcast traffic that has no relevance to them. This leaves the CPU available for more important tasks.

#### Improvements for Multi-Vendor Environments

-----  
As discussed above, multicast addressing reduces the amount of processing that Macintoshes need to do, because NBP lookups are sent to multicast addresses instead of to the general-purpose Ethernet address. However, the biggest improvement that EtherTalk 2.0 offers is that non-AppleTalk nodes

are no longer disturbed by general-purpose Ethernet broadcasts generated by AppleTalk devices. When Macintoshes run only EtherTalk 2.0, they no longer send general-purpose Ethernet broadcasts.

Non-AppleTalk nodes, (that is, Suns, VAXs, and so on) do not register to receive packets sent to Apple's multicast address 09-00-07-FF-FF-FF or Apple's NBP range of multicast addresses 09-00-07-00-00-00 through 09-00-07-00-00-FC. Non-AppleTalk nodes no longer need to spend machine cycles reading Apple-specific Ethernet broadcasts only to learn that they don't need to do anything with them. Many large customers, especially university, government, and Fortune 500 business accounts, will now be more amenable to placing Macintoshes on their Ethernet networks.

Note: TokenTalk 2.0 also uses multicast addressing. The concept is the same: non-AppleTalk nodes on the Token Ring are not disturbed by Apple-specific broadcasts. The exact implementation of Token Ring multicast addressing is different than the Ethernet implementation.

All EtherTalk boards require the EtherTalk Phase 2 driver. For additional information, refer to MacDecathLAN, Fall '88, and the LAN Minds, Spring '89, seminar binders.

## IEEE 802.X LAN Protocols: Brief Descriptions (9/94)

Revised: 9/8/94  
Security: Everyone

IEEE 802.X LAN Protocols: Brief Descriptions (9/94)

Article Created: 2 October 1989  
Article Reviewed/Updated: 8 September 1994

TOPIC -----

I have a question on IEEE 802.X. That is, what should I expect to see for 802.1, 802.2, 802.4, and 802.5?

DISCUSSION -----

The Institute of Electrical and Electronic Engineers (IEEE) was created to establish standards. These standards include Project 802 for specifying interface and protocol specifications for various LAN topologies. The resulting 802 standards correspond with the Physical and Data Link layers of the ISO-OSI Model Layers 1 and 2, the Physical and Data Link layers.

- 802.1 Overview, Interworking and Systems Management
- 802.2 Logical Link Control
- 802.3 CSMA/CD Access Method and Physical Layer Specifications
- 802.4 Token-Passing Bus Access Method and Physical Layer Specifications
- 802.5 Token-Passing Ring Access Method and Physical Layer Specifications
- 802.6 Metropolitan and Network Access Method and Physical Layer Specifications

IEEE 802.1 and 802.2 are still being defined. Furthermore, any associated "packets" aren't going to be seen on the LAN,, because they define the common interface for higher software levels over networks with different topologies, protocols, and media.

IEEE 802.3, 802.4, and 802.5 define different network topologies and media access methods, or the ability of a node to physically send and receive data on a LAN.

Ethernet Data Link Frame Format

-----  
Destination (48 bits), Source (48 bits), Type (16 bits), Data (8n: 46 bytes<= n

<=1500 bytes), CRC (32)

#### 802.3 CSMA/CD Access Method

-----  
Destination (16 or 48 bits), Source (16 or 48 bits), Length (16 bits), Data (8n:  
46 bytes<= n <=1500 bytes), CRC (32)

#### 802.4 Token-Passing Bus

-----  
Destination (16 or 48 bits), Source (16 or 48 bits), Data (8n: our materials  
didn't list the max), CRC (32)

#### 802.5 Token-Passing Ring

-----  
Destination (48 bits), Source (48 bits), Data (8n: max of 4K), CRC (32)

Customizing Fonts: Putting a Tilde where You Want It

=====

Article Created: 6 December 1989  
Article Last Reviewed: 5 November 1991  
Article Last Updated: 5 November 1991

QUESTION -----

Is there a way to use or create special text characters, like the letters e, i, u, y, with a tilde above the character? These characters are used in the native language of the country, Guarani.

RESPONSE-----

As of August, 1989, we couldn't locate any Guarani fonts. Neither the screen fonts supplied by Apple nor the built-in LaserWriter PostScript fonts generally have the diacritical tilde over any of the characters except for the N, n, O, o, and A, a. However, Microsoft Word versions 3.0 and 4.0 have an overstrike ability that lets you put the tilde (or any symbol or character) over any character.

Other possible options are to try to locate a specific Paraguayan Guarani font or to design a screen font and/or a downloadable PostScript font yourself.

There are many programs that let you design your own fonts, including ATF FontMaker by Kingsley and KeyMaster by Altsys. For more details, search the Tech Info Library under "Microsoft," "ATF," or "KeyMaster."

There is also a company called "Linguist's Software", which sells international word processors, fonts, and other assorted software products. Search under their name to find other possible solutions.

## EtherShare: Implements AFP/PAP on UNIX Machines

Revised: 12/13/89  
Security: Everyone

EtherShare: Implements AFP/PAP on UNIX Machines

=====

This article last reviewed: 2 October 1989

TOPIC-----

Do you know of software that can make my UNIX machines act as servers in AppleTalk Internets?

DISCUSSION -----

Yes, the German system house Helios Software GmbH has a file server product named EtherShare.

EtherShare implements an AFP fileserver and PAP printserver on UNIX machines in Ethernet. It supports the well-known AppleTalk and the enhanced AppleTalk Phase 2. You decide during the boot process what AppleTalk version to use. It is also capable of routing AppleTalk packets between several Ethernets, when the UNIX machine has more than one Ethernet interface. EtherShare is installed with very few UNIX commands. This means you can do server administration totally from a Macintosh in the typical Macintosh style.

Currently Supported UNIX Machines

-----

- Sun 3/xx, Sun 4/xx, and Sun 386i under Sun OS 4.0 or higher
- Sony NEWS 1500, 1700, 1800, and 1900 (as of September, 1989, AppleTalk Phase 2, because NEWS's Ethernet driver does not support the IEEE standard for MultiCast).

AFP Functionality

-----

EtherShare fileserver can be used by all AppleTalk clients without any changes in the client AppleShare software. These clients include Macintosh, Apple IIGS, and MS-DOS PCs. It also supports all security and

locking mechanisms, like scrambling of passwords, volume password, MS-DOS short names, drop folders, and so on. EtherShare can be used by up to 200 users simultaneously, depending on the server machine. AppleShare clients can access UNIX files if allowed by the administrator. Likewise, UNIX applications can access files stored by AppleShare clients.

#### PAP Functionality

-----

EtherShare implements a PAP printserver in AppleTalk with as many print queues as you want. You can print to PostScript printers (which are directly, asynchronously attached to the UNIX machine) or to other networked PAP print services in the AppleTalk Internet. EtherShare also lets UNIX applications print to PAP printers, like networked LaserWriters.

#### Installation and Administration

-----

It takes very few UNIX commands to install EtherShare. The administration of AFP and PAP servers is done from any Macintosh in the AppleTalk Internet, in a manner similar to Apple's AppleShare admin program. However, you can administer several EtherShare file servers simultaneously and easily exchange users, user groups, and their privileges between different EtherShare servers.

#### EtherShare APIs

-----

Helios provides a full set of programming interfaces. For example, you can write UNIX applications which respect the AFP-locking.

A/UX 1.1: Compatible Cartridge Drives Needed

=====

This article last reviewed: 3 October 1989

QUESTION-----

I have a Mass Microsystems 45MB removable hard disk cartridge, which uses a Syquest 555 drive. I am trying to use it with A/UX 1.1. Unfortunately, all I'm getting is errors.

RESPONSE-----

We have checked with people at Mass Microsystems, and as of August, 1989, their 45MB removable cartridge drive can work only under Macintosh OS. Because the driver is not compatible with A/UX, someone (third-party developer) needs to write a special driver for it.

If anyone knows of any removable cartridge drives that work under A/UX, please Link TECH.COMM.

## A/UX: System Benchmark Results using lloops

Revised: 1/20/93  
Security: Everyone

A/UX: System Benchmark Results using "lloops"

=====

Article Created: 6 February 1990

### Article Change History

-----

08/31/92 - REVIEWED  
• For technical accuracy.  
01/20/93 - UPDATED  
• Vendor information.

### TOPIC -----

This article describes the floating-point, computational performance of an A/UX system. The benchmark test run was "lloops," a suite of benchmarks, developed at Lawrence Livermore Labs, and written in FORTRAN. In this case, the suites were written both in NKR Research's (now PenWare, Inc.) Optimizing FORTRAN and f77 (shipped with A/UX) compilers.

### DISCUSSION -----

The test system was a Macintosh IICx with 4MB RAM and a HD80 SC hard drive. All tests were done in single-user mode with all networking and the toolbox turned off. All calculations were made on data defined as REAL\*8. Because "lloops" contains a variety of common scientific and math program segments, floating point performance varies by "sub-test". Overall results (using the NKR compiler) were as follows:

Mflops range: 0.0364 to 0.3148 Mflops/sec  
Harmonic mean: 0.1189 Mflops/sec  
Median rate: 0.1319 Mflops/sec +/- 0.0577 Mflops/sec  
Average rate: 0.1496 Mflops/sec +/- 0.0668 Mflops/sec

Results using the f77 were lower by 30% to 60%--presumably because of the lack of an object optimizer with f77.

A/UX: Shift-Click Problem Solved

=====

Article Created: 6 February 1990

Article Change History

-----

08/31/92 - REVIEWED

•For technical accuracy

TOPIC-----

When I'm running A/UX, selecting files under "hfx" by pressing shift-click does not work. What's going on?

DISCUSSION-----

The Shift-click in the A/UX "hfx" behaves a bit differently than in the Macintosh OS. As described in the "Getting Started with A/UX", it works as expected. In general:

- To select a "contiguous" group of files and folders, or files and folders on the same level, press Shift while you select files or folders. You can also select the first file in the group, press Shift and select the last file in the group--all files in between are selected.
- To select files or folders that are "not contiguous", press Command and select the files or folders.

## A/UX: Fix for POSSIBLE FILE SIZE ERROR I=xxx Error

Revised: 11/9/92  
Security: Everyone

A/UX: Fix for "POSSIBLE FILE SIZE ERROR I=xxx Error"

=====

Article Created: 3 October 1989

### Article Change History

-----

08/31/92 - REVIEWED

- For technical accuracy.

### QUESTION -----

When I run fsck on my A/UX system, it shows several possible file size errors and the corresponding inode numbers. Is there any way to fix these files?

### DISCUSSION -----

The "POSSIBLE FILE SIZE ERROR I=xxx" error occurs in the Phase 1 of "fsck" when the file information in the inode table conflicts with the actual file size. With this inconsistency, basically, you can find the file of the inode number, make a copy, and remove it.

For example, with the file system /dev/dsk/c5d0s4 (which encountered the "POSSIBLE FILE SIZE ERROR I=xxx") mounted on /u2, and the inode number 1234 associated with the error, do the following:

- 1) # cd /u2
- 2) # find . -inum 1234 -print  
(It displays the filename path of the inode number 1234.)
- 3) Go to that path and try to make a copy of that file (if it is important).
- 4) Remove that file.
- 5) # cd /
- 6) # umount /u2
- 7) fsck /dev/rdisk/c5d0s4  
(The "POSSIBLE FILE SIZE ERROR" for that inode should go away after "fsck".)

## A/UX: Problem Retrieving Files From Apple 40SC Tape

Revised: 9/29/92  
Security: Everyone

A/UX: Problem Retrieving Files From Apple 40SC Tape

=====

Article Created: 3 October 1989

### Article Change History

-----

08/31/92 - REVIEWED  
• For technical accuracy.

### TOPIC -----

Using an Apple Tape Drive, I tried loading the third-party UNIX applications you shipped to our office on two cartridges. I didn't have directions for extracting the files from the tape, so I used tar. The system replies with a Tape Read Error.

The following commands were unsuccessful:

```
tar -tvf /dev/dsk/t0
tar -tvf /dev/dsk/t1
tar tvf /dev/dsk/t0
tar tvf /dev/dsk/t1
tar -xvf /dev/dsk/t0
tar -xvf /dev/dsk/t1
tar xvf /dev/dsk/t0
tar xvf /dev/dsk/t1
```

The following commands were successful:

```
mt -f /dev/dsk/t1 rewind
mt -f /dev/dsk/t1 fsf 1
```

What did I do wrong?

### DISCUSSION -----

You should have received the instructions to install from the two tapes. The two A/UX demo tapes distributed by A/UX Technical Resources contain many third-party Macintosh/UNIX applications (approximately 80MB). Most of these files are compressed tar format.

The instructions describe in great detail the contents of the tapes, how much space is required, and how to extract files. We would suggest that you get the instructions before trying to extract any files.

In general, instead of `/dev/dsk/`, you should use something like `/dev/rmt/tc`. All logical tape units are stored in the `/dev/rmt` directory. Also, since the Apple 40SC Tape Driver has an 8K buffer boundary in the kernel, you need to state a block factor option in the `"tar"` command.

Macintosh SE-to-Macintosh SE/30 Upgrade: Drive Issues

=====

Article Created: 6 December 1989  
Article Last Reviewed: 23 August 1991  
Article Last Updated: 23 August 1991

TOPIC -----

I have a Macintosh SE with two floppy drives. Can I upgrade to a Macintosh SE/30 with one Apple SuperDrive (formerly Apple FDHD) and one 800K floppy drive?

DISCUSSION -----

It is not possible to upgrade a Macintosh SE with two floppy drives to a Macintosh SE/30 with one SuperDrive and one 800K floppy drive. This is because the Macintosh SE/30 logic board has only one internal floppy-drive connector. When upgrading a dual floppy drive Macintosh SE, you must remove one of the internal floppy drives.

It is possible to upgrade to the SuperDrive without also upgrading to the Macintosh SE/30 logic board. In this case it would be possible to retain both floppy drives.

## TOPS: No Access to AppleShare Driver

Revised: 12/6/89  
Security: Everyone

TOPS: No Access to AppleShare Driver

=====

This article last reviewed: 11 October 1989

TOPIC -----

I want to use AppleShare PC 2.0 with a LocalTalk PC Card to provide print services to a LaserWriter, while continuing to use TOPS to provide file services. Can I?

On a related note, can AppleShare PC use memory above the 640K barrier? Are there any official plans to make it available in the future?

DISCUSSION -----

TOPS doesn't plan to provide access to the AppleShare driver from TOPS, now or in the foreseeable future. Therefore, you must continue to have both the TOPS card and LocalTalk PC Card installed in your system to gain access to both services. This information was provided by TOPS Technical Support.

If you need print services only, you might consider TOPS NetPrint. It is a software package that enables DOS users to print directly to the LaserWriters or other PostScript-compatible printers from within their DOS applications. NetPrint lets DOS users print the full IBM character set, all LaserWriter fonts, and any downloadable fonts.

AppleShare will not load into expanded memory. AppleShare PC 2.0 uses differing amounts of memory based on the options installed, as outlined below:

|                                   |            |
|-----------------------------------|------------|
| File and Print Services:          | 117 - 126K |
| File Services only:               | 91 - 100K  |
| Print Services only:              | 62 - 71K   |
| AppleTalk and MLI driver(s) only: | 49 - 58K   |
| MLI driver(s) only:               | 13 - 22K   |

Add 57K to make the DA memory resident  
Add 6 - 15K per additional MLI driver

## Macintosh SE: Internal HD in Dual Floppy Voids Warranty

Revised: 8/7/92  
Security: Everyone

Macintosh SE: Internal HD in Dual Floppy Voids Warranty

=====

Article Created: 11 October 1989  
Article Last Reviewed: 7 August 1992  
Article Last Updated:

TOPIC -----

If I install a third-party hard disk in a dual-floppy Macintosh SE, will I void the warranty on the Macintosh?

DISCUSSION -----

To answer this question, we looked in the Apple Service Programs binder. The following information is under the "Product Notices" tab on page 8.4.12 (6/15/89 is the revision date):

Macintosh SE and Macintosh II Third-Party Add-Ons (Announced September 87)

The addition of third-party peripherals does not void the Apple Limited Warranty, provide that:

- The addition of the third-party peripheral does not require modification to the design of either the Macintosh II or Macintosh SE.
- If a third-party peripheral requires dealer installation, the installation is performed by an Apple Service Certified Technician. ESD precautions should be followed during installation.
- The total number of internal drives does not exceed two for the Macintosh SE.
- Third-party peripheral cards satisfy Apple specifications for the NuBus architecture in the Macintosh II and the SE-Bus architecture in the Macintosh SE.
- Third-party RAM SIMMs must meet Apple specifications for the CPU they

are installed in.

- Third-party hard drives satisfy the thermal, physical, and electronic specifications stated by Apple for internal SCSI devices.

Based on the statement, "The total number of internal drives does not exceed two for the Macintosh SE", any Macintosh SE configuration that has three internal drives voids the Apple Limited Warranty. Also, any configuration that disrupts the internal thermal dynamics (air flow) of the Macintosh SE voids the Apple Limited Warranty.

## Macintosh Plus: Control Panel Startup Device Not Available

Revised: 6/16/92  
Security: Everyone

Macintosh Plus: Control Panel Startup Device Not Available

=====  
Article Created: 11 October 1989  
Article Last Reviewed: 29 May 1992  
Article Last Updated: 29 May 1992

### TOPIC -----

The Startup Device does not appear in the Control Panel on Macintosh Plus systems. This happens with System 4.3 and with System 6 and later. And using System 7, there is no Startup Disk control panel available either. I have two hard disks and want to choose which one should start up first.

### DISCUSSION -----

That behavior is correct. On Macintosh Plus or earlier Macintoshes, the Startup Device module of the Control Panel does not appear while running System 6.0.X or earlier, nor does the Startup Disk control panel appear while running System 7 or later. The SCSI firmware is different on the Macintosh Plus and does not allow for the same flexibility that later Macintoshes provide. The SCSI device with the highest SCSI number will be the first device to boot (note that an internal hard drive will take SCSI ID 0, while the Macintosh itself will take SCSI ID 7).

For more information, see chapter 18 of "Inside Macintosh Volume V," specifically page 325.

## A/UX: cpio and Floppy Disk Error (2/95)

Revised: 2/27/95  
Security: Everyone

A/UX: "cpio" and Floppy Disk Error (2/95)

Article Created: 12 October 1989  
Article Reviewed/Updated: 27 February 1995

TOPIC -----

I encountered a problem with "cpio". When I try to restore a big file, which was "cpio"-ed on to two floppy disks, in a directory where the file already exists, I get the message:

"can't read input - errno=25: Not a typewriter"

After some retries, the restore succeeds. When I restore the file in a directory where the file doesn't exist, I don't have the problem. It seems that this error occurs when you try a restore from more than one floppy disk and to a directory where the file already exists.

Also, I am now seeing error number 5 on a regular basis.

DISCUSSION -----

We experienced the same problem you encountered with the "cpio", which involved a big file across two floppy disks.

The error saying "not a typewriter" is an historical error. The text for this error message was created when the terminals attached to the system were teletypes. The error is saying that there is no terminal attached to the process where the process can send messages generated by either STDOUT (standard output) or STDERR (standard error). This message is common on processes that are started from a script, from cron or from inittab. It can also be encountered if a process is started as a background process. If the process generates any kind of output, the message "not a typewriter" is displayed.

As we have debugged further, the problem seems to be with either the "cpio" program itself or the floppy driver. We encountered a state where the errno changed to 25 after the "fgets()" function was called while trying to open the current directory.

The "Can't read input - error=25: Not a typewriter" error message appears when specify a block device rather than a character device.

Normally, the "Can't read input - error=5: I/O error" or the "Can't write output - error=5: I/O error" message appears, when the floppy disk was not inserted in the drive before the "cpio" command tries to open the drive. The driver can also give this messge when it detects a bad floppy disk.

This article last reviewed: 12 October 1989

TOPIC -----

I have a NEC LC890 laser printer (a PostScript printer) with a 2-bin sheet feeder, but I can't use it, because with the standard LaserWriter driver you see only one bin. Do you know of a driver that controls two or more bins?

DISCUSSION -----

We contacted NEC Technical Support, and they told us that the NEC LC890 will plug into an AppleTalk network and work with the Apple LaserWriter driver. As you mentioned, only one bin can be seen by this driver. NEC has a patch for the LaserWriter driver that gives you dual-bin support.

NEC told us that this patch is available on their free bulletin board. The number for that bulletin board is 508-264-8816. The patch is in the Apple section. It is called "dual-bin support" (LaserWriter driver 5.2/6.0), and the filename is "dualbin.sit." There is a patch that works with LaserWriter driver 5.2 and a patch that works with LaserWriter driver 6.0, plus documentation included in this StuffIt package.

The patch gives a different print dialog for you to select different bins. Other printers on the network, like an Apple LaserWriter, appear the same as they do now. The print dialog does not change for them.

## QuickDraw: How It Does Pattern Alignment

Revised: 12/6/89  
Security: Everyone

QuickDraw: How It Does Pattern Alignment

=====

This article last reviewed: 12 October 1989

TOPIC -----

I need to know how QuickDraw aligns its patterns when it's drawing them. I'm using off-screen bitmaps to get patterns that always start in the same place, but a less memory-intensive solution would be nice. Is there a way to do this?

DISCUSSION -----

QuickDraw aligns patterns relative to the origin of the current GrafPort, which is usually a window. The origin of a window is the upper lefthand corner of the window. This causes a pattern to "shift" within a pattern-filled rectangle if that rectangle is placed in different locations within a window. The method of drawing a filled shape in an off-screen bitmap and then placing it in the current window is an acceptable method for forcing a pattern's placement within that filled shape.

## Macintosh: Remote Power Up (12/93)

Revised: 12/22/93  
Security: Everyone

Macintosh: Remote Power Up (12/93)

Article Created: 13 October 1989  
Article Reviewed/Updated: 22 December 1993

TOPIC -----

I want to remotely power up and remotely reset a Macintosh computer? Are there Apple or third party solutions available?

DISCUSSION -----

Depending on the Macintosh model you have, there are different software and hardware solutions available. Many Desktop (examples: Macintosh IIfx, IIfx) and PowerBook models are capable of being remotely powered up or restarted.

Below are a few examples of some solutions.

- Farallon Timbuktu/Remote Pack includes a cable and software that allows a Macintosh to be started remotely. For further details, contact the vendor, Farallon. To obtain contact information, use "Farallon" as a search string.
- PowerKey is a hardware and software solution for compact and modular desktop Macintoshes. For further details, contact the vendor, Sophisticated Circuits. To obtain contact information, use "Sophisticated Circuits" as a search string.
- If a Macintosh is powered on and is connected to an AppleTalk network, you can use third party network management software to restart Macintoshes over the network. GraceLAN Update Manager by TechWorks and Status\*Mac by ON Technology are two examples. Use the vendor as a search string for contact information for these companies.
- For PowerBook computers, you can use the Auto Wake Up feature in the PowerBook control panel to set a time for your PowerBook to automatically "wake up."

Macintosh II, IIfx computers: Special Information

-----  
The information below describes how to modify the Macintosh II and IIX models, which don't have the auto power capability. One of the scenarios suggested is how the PowerKey product works.

If you want to modify the Macintosh, consider the following. The way to power up the Macintosh II without pressing a button requires a modified power supply or a completely different one. There is circuitry in the Macintosh II power supply that senses a level transition from the logic board, initiated by pressing either the button on the back of the machine or the reset key on the ADB keyboard. If this transition does not occur, the power-up sequence does not start. If a steady voltage is applied to the Power Fail signal line into the power supply, the sequence will not start. The power supply must see the transition to begin the power-up cycle. A modified power supply that powers up with a voltage applied steadily, instead of level-shifted, would work in this case.

To replace the switch on the back with a power-sensing switch, you must ensure the proper connections are made, because the switch is a double-pole, double-throw switch. Also, the new switch needs to perform the same function as the existing mechanical one. That is, it must switch ground into the shutdown circuit to shut off the system. Likewise, to turn the system on, it must switch power in. This is not to say it cannot be done. Just make sure the functions of the power-sensing switch are the same as the current mechanical one.

Another possibility may be to create a circuit that plugs into the ADB port and generates pulses of a sufficient amplitude (between 3.0 and 6.8VDC) and duration (>1.5 seconds) on the proper pins (2 and 4) to operate the Power Fail circuit in the present power supply long enough to bring it up. Perhaps a remote ADB switch would work, too. It would need to momentarily connect pins 2 and 4 on the ADB port.

## MacWorkStation: A Pseudo-TLPM Workaround

Revised: 12/6/89  
Security: Everyone

MacWorkStation: A Pseudo-TLPM Workaround

=====

This article last reviewed: 13 October 1989

TOPIC -----

Is there a plan to provide a TLPM to run MacWorkStation over the TokenTalk NB Card?

DISCUSSION -----

Providing a TLPM (Transport Layer Protocol Module) to let MacWorkStation run over Token Ring is under investigation. There is no timeframe for implementing it.

As of September, 1989, you can use MacWorkStation over the Apple TokenTalk NB Card via ADSP (Apple Data Stream Protocol), as if you created a pseudo host application on another Macintosh.

## A/UX 1.1: pstat -m Option Problem

Revised: 9/30/92  
Security: Everyone

A/UX 1.1: "pstat -m" Option Problem

Article Created: 12 October 1989

### Article Change History

-----  
08/31/92 - REVIEWED  
    • For technical accuracy.  
08/31/92 - UPDATED  
    • To include A/UX 3.0 Information.

### TOPIC -----

This article discusses a "pstat -m" option problem.

### DISCUSSION -----

The "pstat -m" option should report about core memory allocations and give a dump of the memory free map with headings about

- core addresses(LOC)
- click addresses (ADDR)
- sizes of clicks (SIZE).

However, when you type "pstat -m", you get a general report about buffers, inodes, procs, file table (type the -a option), and an empty report with no entries about LOC, ADDR, and SIZE.

At the end of the report, you get a statement similar to:

"Total memory = 1023K, currently free = 0K."

This message appears whether it is a non-loaded or even heavily-loaded system (running 5 nntp sessions, nfs, crunching C code, and so on).

This is a problem in A/UX 1.1, not your particular kernel. This problem has been fixed in A/UX 2.0.

## Ethernet: NFS-to-ATP Translation Over Backbone

Revised: 10/15/90  
Security: Everyone

Ethernet: NFS-to-ATP Translation Over Backbone

=====

This article last reviewed: 10 October 1990

TOPIC -----

I want to connect to an Ethernet backbone to which personal IRIS workstations are connected. I want to do NFS-to-AFP translations. Basically, I want to do the same thing that the Cayman GatorBox does, but I want to eliminate the GatorBox and connect directly. The personal IRIS workstations are UNIX machines; their UNIX adheres to TCP/IP standards. We are looking for a supported solution. I would rather not get Telnet using Excelan's EtherPort SE/30 and host access for the Macintosh. I would rather mount directories onto my Macintosh. Can I do this without a GatorBox?

DISCUSSION -----

Yes, You can do this without a GatorBox by getting the CAP (Columbia AppleTalk Package for UNIX), a public domain software from Columbia University. Here are CAP's prerequisites:

- Kinetics FastPath box
- KIP, a revision of the UDP software, developed by Bill Croft at Stanford University
- Based TCP/IP host running UNIX

For the above CAP/KIP/AUFS solution, basically, the customer needs to install the CAP software on the UNIX host and download the KIP code to the Kinetics FastPath box. The client Macintosh side can run on either LocalTalk or EtherTalk.

For more information on CAP and KIP, search under these words in the Tech Info Library. Also, pay particular attention to the Tech Info Library articles "UNIX: Kip and Cap Information," "Macintosh: Columbia AppleTalk Package And AUFS," and "Macintosh-To-Sin Connectivity."

## AppleShare PC 2.0: Not Recommended on Single-Drive PC

Revised: 12/6/89  
Security: Everyone

AppleShare PC 2.0: Not Recommended on Single-Drive PC

=====

This article last reviewed: 13 October 1989

TOPIC -----

When installing AppleShare PC on a machine with one 5.25-inch disk remember that it really has two logical drives, A: and B:. To test this at DOS, issue this command:

DISKCOPY A: B:

The DOS DISKCOPY program prompts you to switch disks with a message like

"Please insert the diskette for drive A:."

Because I haven't had a chance to use AppleShare PC 2.0, I don't know how the installer batch file is written. If it asks for drives by drive letter, I'd try specifying A: and B: and let DOS ask you to do a disk swap.

DISCUSSION -----

You are correct that the AppleShare PC 2.0 installer can install from A: to B:--even when B: is just a logical drive. DOS prompts for each disk as it is needed. Unfortunately, because of the installer program's design, this might require swapping disks as many as 100 times--even for print services alone.

This means that we do not recommend installing AppleShare PC 2.0 using a system that has only one floppy drive and no a hard disk. Booting such a system with already installed disks works fine. However, unless you enjoy swapping disks, don't try to install on it.

As a side note, the installer is actually an executable file, not a batch file. You can write a batch file to do the install by using the xcopy command on groups of files. This shortens the install process a great deal and allows installing with a single drive PC. Of course, it also requires manual preparation of AUTOEXEC.BAT and NET.CFG and selection of the proper REDIR file,

depending on what version of DOS is being used.

## Use MacLink Plus 3.X With Wang VS Release 7

Revised: 12/6/89  
Security: Everyone

Use MacLink Plus 3.X With Wang VS Release 7

=====

This article last reviewed: 13 October 1989

TOPIC -----

I am using MacLink Plus/Wang VS 2.02 to connect the Macintosh to a Wang VS model 15 running the VS release 7 operating system for terminal emulation using direct cable to an ADC port. When connection is established, I get the logon VS screen--but that's all. The characters entered for userid and password don't seem to be accepted by the VS; the Macintosh beeps with each keystroke.

DISCUSSION -----

We talked with DataViz Technical Support, and they confirmed that versions of MacLink Plus prior to version 3 do not work properly with VS release 7. They suggested that you should upgrade to the latest version which is 3.06. According to DataViz, they currently have a free upgrade program in place.

For more in-depth support on their product, we suggest you contact them directly. For more their addresses and numbers, search the Tech Info Library under "DataViz."

## Macintosh: Database File Conversion

Revised: 12/6/89  
Security: Everyone

Macintosh: Database File Conversion

=====

This article last reviewed: 13 October 1989

TOPIC -----

I need to transfer database information from a Tandy system running an ENABLE-based program called Legis and a program called Q&A to Microsoft Works. Do you know how to do this?

DISCUSSION -----

We are not familiar with either Legis or Q&A. However, you can transfer data from one database to another by way of several different methods. Any of these methods is fairly straightforward. The object is to find a common link between the two systems and their associated databases. This may be matching file formats, a common file format, the ability to import data from a text file, or being able to read an incoming data stream.

You may be able to use a common file format, like DIF or SYLK, or save the database information to a text file and use the import feature within Microsoft Works to retrieve the information. In either case, you should be able to move the file from the Tandy to the Macintosh via the Apple PC 5.25 drive and Apple File Exchange.

If you do not have access to an Apple PC 5.25 drive, the database-generated text file also can be transferred between the systems using either PC MacLink or a direct serial connection with a terminal package running on both systems.

Another method of moving the information would be to use a network solution, like TOPS or AppleShare PC, making the database files available to everyone. Again, to make this a working solution, use a common file format.

## Mutoh Plotter: Macintosh Compatibility

Revised: 12/6/89  
Security: Everyone

Mutoh Plotter: Macintosh Compatibility

=====

This article last reviewed: 13 October 1989

TOPIC -----

I need compatibility information about the Mutoh plotter series, especially IP-500 and IP-530. Which Macintosh software can drive it? Will MacPlot Professional drive it? Which standard plotters (if any) are these Mutoh plotters compatible with? The data sheets only say that they are HPGL-compatible.

DISCUSSION -----

We contacted the Mutoh Sales Office in Southern California and found that the IP-500 emulates an HP-7580. All they had to say about the IP-530 was that it is HPGL-compatible. It doesn't emulate any specific plotter. The folks at Microspot (MacPlot driver) would not guarantee that the Mutoh plotters would work with their product, because they haven't been tested. They stated that there should be no problem driving any HPGL-compatible plotter.

## Works-to-Works/AppleWorks 3.0: Saves Files in ASCII

Revised: 12/6/89  
Security: Everyone

Works-to-Works/AppleWorks 3.0: Saves Files in ASCII

=====

This article last reviewed: 13 October 1989

TOPIC -----

The name Productivity Software, Inc. appears in the "Get Info" dialog box for the AppleWorks-to-Microsoft Works translator for Apple File Exchange. This translator does not support the new AppleWorks 3.0.

I am receiving a rash of complaints about backward and forward compatibility surrounding AppleWorks 3.0. Is anyone else getting these complaints? It seems that version 3.0 will not read older 1.x files and will not allow the user to save files in older 1.x or 2.x formats.

I am trying to find out if there will be an upgrade? Does anyone have the phone number for Productivity Software, Inc. or know where they are located?

DISCUSSION -----

CLARIS Tech Support is telling their customers to save the files as ASCII for Works-to-Works to function as expected. Using the new features causes AppleWorks 3.0 to use a different creator type, which is not recognized by Works-to-Works. The phone numbers we have for Productivity Software are no longer valid. However, they do still have an active AppleLink account (D0002). We are sending them a copy of this Link.

CLARIS was unaware of problems reading files saved by older versions of the software. As long as no new features are used, AppleWorks 3.0 saves files in a format that can be read by older versions of the software. Once a new feature is used, the creator type is changed and is no longer readable by older software. This is intentional because the old software would get confused when trying to deal with the results of a new feature. Again, they suggest saving the file in ASCII form for reading into previous versions. For further clarification, call CLARIS Technical Support. For more details, search the Tech Info Library under "CLARIS"

## AppleShare Print Server: Installing Software

Revised: 2/6/90  
Security: Everyone

AppleShare Print Server: Installing Software

=====

This article last reviewed: 13 October 1989

TOPIC -----

The AppleShare Print Server Administrator's Guide refers to a "Server System" that should be used when installing a server see (page 16, instruction 5).

What happens when a user wants to set up a server on a 68030-based machine that needs System 6.0.3? This is not provided for in the Server Software package. Because the standard System Software is the only way to obtain System 6.0.3, could this cause problems?

DISCUSSION -----

When installing the AppleShare Print Server on a Macintosh 512Ke, it is important to install the System Software using the AppleShare Print Server installer disk. This guarantees that the AppleShare Print Server software is running in conjunction with System Software that supports both the Macintosh 512Ke and the Print Server software.

On the Macintosh Plus and later Macintosh systems, we recommend installing the System Software from a disk containing the most recent version of System Software available for that particular machine. For example, you should install System Software 6.0.3 for the Macintosh IIcx. Then install the AppleShare Print Server software.

## Macintosh System Software 6.0.4: General Information

Revised: 12/6/89  
Security: Everyone

Macintosh System Software 6.0.4: General Information

=====

This article last reviewed: 13 October 1989

TOPIC -----

This article is a general discussion of Macintosh System Software 6.0.4.

DISCUSSION -----

The Macintosh IIci and Portable REQUIRES Macintosh System Software 6.0.4 or later. Trying to boot either of these computers from versions earlier than 6.0.4 results in a dialog box that reads "This startup disk was created with a 'Minimum' installer script and will not work on this model Macintosh. Use a standard installer script to update the disk for different models.".

The only people who need to upgrade to 6.0.4, are those who will be using the Macintosh IIci or the Portable. In both cases, 6.0.4 is included. Most of the changes that occurred in 6.0.4 were required by the IIci and Portable hardware. Some of the more significant changes to 6.0.4 include:

- The Multi-Disk Installer is introduced with 6.0.4.
- The Sound Manager was modified to use the Time Manager to provide fixed frequency timing.
- The SysEnvirons call has been modified to support the new computers.
- Responder has been modified to recognize the new computers.
- Code to support IIci parity is included in 6.0.4.
- A new version of the Monitors cdev is included with 6.0.4 which supports direct video modes, improved grayscale video modes, and third-party extensibility. On the Macintosh IIci, Monitors also includes special extensions so the sophisticated user can control the amount of RAM dedicated to built-in video.

- The Battery DA was added so users could monitor the power level of the Macintosh Portable battery.
- The Portable cdev is included in 6.0.4. This lets users change various settings for the Macintosh Portable.
- CloseView 1.1 is included in 6.0.4. This version has a better interface than 1.0.

Macintosh System Software 6.0.4 will also be included with all Macintosh models as of the IIci introduction. This version will also be rolled into the stand-alone Macintosh System Software package.

Those who have subscriptions to the Macintosh System Software update service will also receive 6.0.4.

## HyperCard 1.2.2: Problem With SAM 1.0

Revised: 12/6/89  
Security: Everyone

HyperCard 1.2.2: Problem With SAM 1.0

=====

This article last reviewed: 26 October 1989

TOPIC -----

I experienced a problem with HyperCard 1.2.2 and SAM v1 (Symantec AntiVirus for the Macintosh). When I launch an application from within HyperCard and quit the application with SAM installed, control returns to the Finder, not to HyperCard. I fixed the problem by removing SAM. Obviously, the problem does not occur under MultiFinder, because HyperCard stays open when launching another program. Although the problem was spotted under SAM v1, it also afflicts SAM v1.1.

DISCUSSION -----

The problem you describe is known to Symantec and is reported to be documented in the "Read Me" file distributed with SAM 1.1. The "Read Me" file contains information on other known problems and is considered good reading for all users of SAM.

Symantec indicated that this was something they wanted to fix in the next release of the product. No date is set for future releases of SAM.

## MacroMaker: How To Simulate a Pause

Revised: 5/14/92  
Security: Everyone

MacroMaker: How To Simulate a Pause

=====  
Article Created: 26 October 1989  
Article Last Reviewed: 14 May 1992  
Article Last Updated:

### TOPIC -----

Is there any way to put in wait states or time delays into a MacroMaker recording?

### DISCUSSION -----

MacroMaker has no built-in pause function, but it is possible to simulate a pause by recording an extended mouse-button press. To create a simulated pause while recording your macro, press and hold the mouse button for the desired length of the pause. When you play back the macro, the extended mouse button press is played back using the same amount of time as when it was recorded.

Be careful to press the mouse button with the mouse pointer in an unimportant part of the screen. For instance, do not pull down a menu to create the pause or important activities may be suspended for its duration. Your best bet may be to hold the mouse button down while the pointer is in a lower corner of the screen, to avoid affecting the operation of other software.

## Legislative-Information Databases: A List

Revised: 12/17/91  
Security: Everyone

Legislative-Information Databases: A List

=====

Article Created: 9 November 1989  
Article Last Reviewed: 10 August 1992  
Article Last Updated: 14 May 1991

TOPIC -----

Can you give me a list of services that provide electronic access to legislative-information databases?

DISCUSSION -----

So many services provide electronic access to legislative-information databases that we cannot describe them all. Here is a brief list of those that seem most appropriate with contacts for each:

LEGI-SLATE

-----

Legi-Slate, Inc.  
777 North Capitol, Suite 900  
Washington, DC 20002  
202-898-2300

Updated daily. Available on-line via LEGI-SLATE.

LEGI-SLATE reports federal legislative and regulatory information. It comprises the following six services: Congressional Service, Federal Register Service, Bill Text Service, Member Profile and Rating Service, News Service, Press Briefing Service.

CQ Weekly Report

-----

Congressional Quarterly Inc.  
1414 22nd St., N.W.  
Washington, DC 20037  
202-887-6353

Updated weekly. Available on-line via DataTimes as the CQWEEK file.

CQ Weekly Report covers U.S. Congressional and political activity, including legislation and election news. It reports on legislative proposals, decisions, and historical backgrounds; interest group lobbying; and Supreme Court decisions. CQ provides pre-election forecasts, post-election analysis, candidate and new member profiles, and vote studies.

#### Congressional Activities

-----

Oliphant Washington Services (OWS)  
1819 H St., N.W., Suite 330  
Washington, DC 20006-3677  
202-296-0924

Updated weekly. Available on-line via NewsNet, Inc.

Congressional Activities provides information on upcoming congressional events related to the environment and the energy industry. It includes a schedule of hearings, historical background information on scheduled actions, a list of bills and resolutions introduced, reports files, measures passed, laws enacted, and Congressional Record references.

#### Congressional Record Abstracts

-----

National Standards Association, Inc. (NSA)  
1200 Quince Orchard Blvd.  
Gaithersburg, MD 20878  
301-590-2300

Updated weekly. Available on-line via DIALOG Information Services, Inc.

Congressional Record Abstracts summarizes the legislative and policy proceedings reported in the Congressional Record, the official journal of proceedings of the United States Congress.

#### Electronic Legislative Search System (ELSS)

-----

Commerce Clearing House, Inc. (CCH)  
4025 W. Peterson Ave.  
Chicago, IL 60646  
312-583-8500

Updated daily. Available on-line via GE Information Services.

CCH provides a complete, up-to-date history of all legislative activity in current sessions of all state legislatures and the U.S. Congress.

For information on connect services, search the Tech Info Library under "DataTimes," "DIALOG," "LEGI-SLATE," and "GE."

## Macintosh: How To Call ExitToShell Trap from ROM Debugger (9/94)

Revised: 9/6/94  
Security: Everyone

Macintosh: How To Call ExitToShell Trap from ROM Debugger (9/94)

Article Created: 26 October 1989  
Article Reviewed/Updated: 06 September 1994

TOPIC -----

What is the A ("ExitToShell") trap or address to call for "Resume OS" from the ROM debugger on a Macintosh?

DISCUSSION -----

The most efficient way to call the "ExitToShell" trap with any Macintosh with the ROM debugger is documented below. To use this method, the interrupt switch must first be depressed to generate the debugger window.

At the ">" ROM debugger prompt, type the following lines, pressing Return after each:

```
SM 0 A9F4  
G 0
```

In the first line, the "SM" stands for "Set Memory", the "0" signifies memory location "0", and the "A9F4" is the trap number for the "ExitToShell" trap. This line puts "A9F4" at memory location "0". In the second line, the "G" stands for "Go" and the "0" stands for memory location "0". This line tells the computer to execute the instructions starting at memory location "0". Since "A9F4" is at memory location "0", the "ExitToShell" trap is executed.

Barring other memory corruption, your Macintosh should exit back to the Finder. It is recommended that all other work in progress be saved and that the machine be restarted to completely clear and reset memory.

## Macintosh II: Old and New Video Card Part Numbers, Etc.

Revised: 12/6/89  
Security: Everyone

Macintosh II: Old and New Video Card Part Numbers, Etc.

=====

This article last reviewed: 26 October 1989

TOPIC -----

The Macintosh II Video Card specifications seem to have changed since August 15th. After looking in the Finished Goods Price List, the part numbers have actually been replaced. The cards use to be M0213 and M0322. We need to know the changes that have occurred because the video output on their projection monitors now is blurred.

DISCUSSION -----

Actually, Apple part number M0213 is the Macintosh II Video Card 4-Bit Expansion Kit and Apple part number M0322 is the new Macintosh II 4-Bit Video Card. The Macintosh II 8-Bit Video Card is part number M0324. The old 4-Bit Video Card's part number is M0211, and the old 8-Bit Video Card's part number is M5640.

The new video cards (M0322 and M0324) use pin 4 to detect the type of monitor attached to the card, and this feature is probably the cause of the problem. For more information on the new video cards, check the Tech Info Library article, "Macintosh II High-Resolution Video Card: New Features."

## AppleShare PC 2.0: Token Ring Card Memory Location Solution

Revised: 12/6/89  
Security: Everyone

AppleShare PC 2.0: Token Ring Card Memory Location Solution

=====

This article last reviewed: 1 November 1989

TOPIC -----

Problem:

I tried installing AppleShare PC 2.0 on a PS 2 Model 60. The model 60 has 5MB RAM with a 40MB hard drive. Slots 1 and 2 are empty, slot 3 has an extended memory card, slot 4 has a MicroChannel Adapter A Token Ring card (16/4), slot 5 is empty, and slot 6 has an IRMA board.

The problem is that we are getting the "Mem 2 not matching board" error. We have tried many different memory configurations, and the results are always the same. I cannot get a match. What's the problem?

DISCUSSION -----

This error message, along with the description of the system, suggests that you may not have configured the Token Ring card. Configure the card using the IBM Reference Disk, prior to installing AppleShare PC.

Check to see if the files on other disks that may have shipped with the Token Ring card are already contained on the Reference Disk. If not, copy them to the Reference Disk. Make a note of the parameter settings for the card, particularly the memory locations you assigned. You'll need these later, when you install the AppleShare PC software. Start up your PC with the Reference Disk and install and configure the Token Ring card.

## GS/OS 5.0: Slow Startup Time on Network

Revised: 12/6/89  
Security: Everyone

GS/OS 5.0: Slow Startup Time on Network

=====

This article last reviewed: 1 November 1989

TOPIC -----

I am unhappy with the performance of GS/OS 5.0 (not 5.0.2) when starting up 16 Apple IIGS systems over a network. It seems that the startup time has increased by about 10 minutes.

Additionally, there are problems with the workstations losing their Chooser settings. It seems to happen at least hourly.

DISCUSSION -----

The additional time required to start up is caused by the increased size of GS/OS 5.0. Roughly speaking, the increased time works out to about 30 second per Apple IIGS (not that long, considering the amount of data being moved).

The problem of lost Chooser settings has been fixed in version 5.0.2.

## Macintosh: Scan Rates for Monitors (2/95)

Revised: 2/21/95  
Security: Everyone

Macintosh: Scan Rates for Monitors (2/95)

Article Created: 25 November 1989  
Article Last Reviewed/Updated: 21 February 1995

TOPIC -----

This article contains a list of scan rates of Macintosh monitors. Here are two terms you need to understand when reading the tables:

### Scan Rates -----

The scan rate is the time it takes a monitor's electron gun to move across one line of the screen or repeat one entire screen. These values are known as the horizontal and vertical scan rates, respectively. The monitor scan rate is the number of times a screen is redrawn each second. Computer display scan rates differ from standard video scan rates.

### Interlaced versus Non-Interlaced Scans -----

Apple monitors use a non-interlaced, or progressive, scan. Interlacing is a technique used on character-based displays to create solid character text. It is also used on home television sets (the dominant standard in the United States being NTSC). Using alternate scan lines, the monitor performs high-speed retraces to create the illusion that the monitor has twice as many lines as it does. A major drawback of interlaced displays is their tendency to noticeably flicker thin horizontal lines, lines that are frequently used on the Macintosh interface.

The non-interlaced format used on Apple Macintosh monitors means that the horizontal and vertical scan rates are timed to cause the display electron guns to produce even progressively horizontal scans. The non-interlaced scan format helps prevent the flickering that you can see on some types of monitors.

### DISCUSSION -----

Scan rates for Macintosh monitors:

| . | Vertical | Horizontal |
|---|----------|------------|
|---|----------|------------|

|                           | (Hz)  | (KHz) |
|---------------------------|-------|-------|
|                           | ----- | ----- |
| Built-in monitors:        |       |       |
| . Macintosh 128K          | 60.15 | 22.25 |
| . Macintosh 512K          | "     | "     |
| . Macintosh 512Ke         | "     | "     |
| . Macintosh Plus          | "     | "     |
| . Macintosh SE            | "     | "     |
| . Macintosh SE/30         | "     | "     |
| . Macintosh Classic       | "     | "     |
| . Macintosh Classic II    | "     | "     |
| . Macintosh Color Classic | "     | 24.48 |
| . Macintosh LC 520        | 66.7  | 35    |

Apple and Macintosh Monitors:

|                                    |       |      |
|------------------------------------|-------|------|
| . Apple 21-in. Color Display       | 75    | 68.7 |
| . Apple Two-Page Monitor           | 75    | 68.7 |
| . Apple 16-in. Color Display       | 75    | 50.0 |
| . Apple Portrait Display           | 75    | 68.9 |
| . Apple AudioVision 14 Display     | 66.7  | 35   |
| . Macintosh (14-in.) Color Display | 66.7  | 35   |
| . Basic (14-in.) Color Monitor     | 59.94 | 31.5 |
| . Performa Plus Display            | 66.7  | 35   |
| . Performa Display                 | 66.7  | 35   |
| . 13-in. AppleColor High-Res       | 66.7  | 35   |
| . RGB Monitor                      |       |      |
| . 12-in. Apple High-Res            | 66.7  | 35   |
| . Monochrome Monitor               |       |      |

Multiple Scan Monitors:

Apple Macintosh multiple scan monitors let users customize and adjust the size and position of the displayed image.

|                                  |            |          |            |  |
|----------------------------------|------------|----------|------------|--|
| . Apple Multiple Scan 15 display |            |          |            |  |
| . Mode                           | Resolution | Vertical | Horizontal |  |

| .                                | Macintosh | 1024x768   | 75.0     | 60.2       |
| .                                | 1024x768  | 1024x768   | 60.0     | 48.3       |
| . Apple Multiple Scan 20 display |           |            |          |            |
| .                                | Mode      | Resolution | Vertical | Horizontal |
| .                                | ----      | -----      | -----    | -----      |
| .                                | VGA       | 640x480    | 59.95    | 31.47      |
| .                                | Macintosh | 640x480    | 66.7     | 35.0       |
| .                                | VESA      | 640x480    | 75.0     | 37.5       |
| .                                | VESA      | 800x600    | 75.0     | 46.9       |
| .                                | Macintosh | 832x624    | 75.0     | 49.73      |
| .                                | Macintosh | 1024x768   | 74.93    | 60.24      |
| .                                | VESA      | 1024x768   | 75.0     | 60.02      |
| .                                | Macintosh | 1152x870   | 75.0     | 68.7       |
| .                                | VESA      | 1280x1024  | 75.0     | 79.98      |

In some cases, it may be necessary to reset the display settings of a multiple scan monitor to their factory defaults.

To reset these monitors, hold down Control button (which has the circle symbol above it), while pressing the Reset button (which has the triangle symbol).

Most of the time, just pressing the Reset button resets the display settings. However, pressing Control-Reset resets the CPU inside the Multiple Scan 17 Display and Multiple Scan 20 Display.

## Apple Products Meet the CISPR 22 Standard

Revised: 12/13/89  
Security: Everyone

Apple Products Meet the CISPR 22 Standard

=====  
This article last reviewed: 25 November 1989

TOPIC -----

Does the Macintosh family of computers meet the "CISPR 22" standard? Are there any stickers for "CISPR 22" approval on the back of Macintosh computers that are sold in France or any other European countries?

DISCUSSION -----

Apple products DO meet the CISPR Publication No. 22 requirements.

The international committee on RFI (Radio Frequency Interference) -- known as CISPR -- proposed an RFI standard applicable to all Information Technology Equipment (ITE). This proposal was agreed upon by many nations, including -- but not limited to -- Australia, Austria, Belgium, Bulgaria, Canada, Denmark, Egypt, France, Ireland, Italy, Japan, Netherlands, Poland, Romania, South Africa, Spain, Sweden, Turkey, United Kingdom, U.S.A., and U.S.S.R.

As mentioned before, our products meet the CISPR Publication No. 22 requirements.-- which (as of November, 1989) aren't legally required or policed by any of the countries to which we sell products. Neither is any sort of mark or symbol that indicates a product passes the CISPR standards presently required. Labels WILL be required, but probably not until 1992. The CISPR mark will include the letters "EC" for European Conformity.

The European Computer Manufacturers' Association (ECMA) published a CISPR look-alike specification so that its members could prepare themselves in advance of when the CISPR document was published in August 1985. Therefore, you may hear that standard referred to as:

|                      |                                                                                  |
|----------------------|----------------------------------------------------------------------------------|
| ECMA 95 (March 1985) | Information Technology Equipment Limits of interference and measurement methods. |
|----------------------|----------------------------------------------------------------------------------|

Apple Manufacturing in Cork will add FTZ numbers to product labels for those

countries requiring VDE testing; otherwise, there are no special "RFI" marks or symbols on Apple products sold in Europe. Canada, though supporting CISPR, had already aligned its RFI standard to that of the FCC in the U.S.A., and uses a mark that looks like the characters "SA" encircled by a letter "C":

Products destined for sale in the U.S.A. have an FCC approval number.

## Broderbund Software: Problems with Apple IIGS 1MB Systems

Revised: 12/13/89  
Security: Everyone

Broderbund Software: Problems with Apple IIGS 1MB Systems

=====

This article last reviewed: 25 November 1989

TOPIC -----

I'm having various software compatibility problems with the new Apple IIGS 1MB system. Specifically, there are problems with Broderbund's Print Shop GS. Can you tell me anything about this?

DISCUSSION -----

Broderbund Software is aware of the Print Shop GS compatibility issue and they have an update available. Contact Broderbund for more information on the updating procedure.

Broderbund also said that the Apple IIGS-specific versions of the "Carmen Sandiego" series might encounter difficulties with System 5.0x and the 1MB Apple IIGS computer. Tool 032 is required by these applications, and may be missing after an installation of System 5.0x.

To resolve this issue, locate a disk with Tool 032 and copy that tool into the Tools folder of the system disk to be used with the Carmen Sandiego.

For more information, search under: "Broderbund"

## Limits On Call Of Programming Resources

Revised: 12/13/89  
Security: Everyone

Limits On Call Of Programming Resources

=====

This article last reviewed: 25 November 1989

TOPIC -----

I am trying to write an application. Is there a limit on the number of resources a program can call? (A resource here would be a memory block that is periodically filled with incoming data and then called from an application.)

DISCUSSION -----

The theoretical limit on the number of resources an application can open at one time greatly exceeds the practical limits of a program.

If you are not using "owned" resources, such as resources for desk accessories, you can have up to 32767 of a single resource type. If each of those resources held 1Kb of data, you would be accessing on the order of 30MB. In other words, the limit on the number of resources you can have open at one time is not a real limit in the way that the limit on the number of open files is.

If you are considering having thousands of resources open at one time, we suspect that you need to take a hard look at the way you are doing things and develop an alternative method for accessing data.

(NOTE: Tech Note #141 states that the maximum number of resources you can have in a single file is 2727. Also, be aware that the size of a resource fork of a single file is limited to 16MB. This probably isn't an issue, but it has been brought to our attention at least once.)

## AppleShare: Documentataion On Desktop Calls

Revised: 12/13/89  
Security: Everyone

AppleShare: Documentataion On Desktop Calls

=====

This article last reviewed: 25 November 1989

TOPIC -----

Where are the new desktop calls (OpenDB, AddIcon, AddComment, and so on) documented? I've noticed that our AppleShare servers support the "new" Desktop Manager, but I haven't been able to find any documentation on it. Can you help?

DISCUSSION -----

The desktop calls such as FPAAddIcon are documented in two places: Inside AppleTalk and the AppleTalk Filing Protocol (AFP) Engineering Technical Notes. Both of these are available from APDA. For programming purposes, we recommend the Technical Notes; we suggest Inside AppleTalk for a theoretical understanding of the internals of AppleTalk.

(NOTE: These calls are currently available only for AppleShare. They are not supported for local volumes.)

## Macintosh II High-Resolution Video Card: Monitor Sensing

Revised: 12/13/89  
Security: Everyone

Macintosh II High-Resolution Video Card: Monitor Sensing

=====

TOPIC -----

This article lists the pin configurations to use with the Macintosh II High-Resolution Video Card, so that its monitor-sensing function will work properly.

DISCUSSION -----

The Macintosh II High-Resolution Video card is the replacement card for Macintosh II Video card. One new feature with this card which may present a problem is the automatic monitor sensing.

This feature, which has been incorporated into the video card for the Portrait and Two-Page display, allows the video card to determine if a monitor is attached to the card at boot time. This is accomplished by sensing either a low (ground) or high (no connect) signal on the connector.

For DB-15 connectors, these sense lines are on pin 4, 7 and 10. The Macintosh II High-Resolution Video card is a special case and only senses pin 4 of the DB-15 connector.

In order for the card to work correctly with the monitors listed below, the following is the minimum configuration of pins that must be connected:

| Pin | Video Card Signal  | Mac       |   | Mac      |          |
|-----|--------------------|-----------|---|----------|----------|
|     |                    | Hi-Res    |   | Hi-Res   |          |
|     |                    | Mono Pins |   | RGB Pins |          |
|     |                    |           |   |          | A II     |
|     |                    |           |   |          | RGB Pins |
| 1   | Red video ground   | ->        |   | 1        | 1        |
| 2   | Analog red video   | ->        |   | 2        | 2        |
| 3   | TTL composite sync | ->        | 3 | 3        | 3        |

| 10    | Sense 2 (not used)                |    |       |       |       |
| 11    | Ground                            |    |       |       |       |
| 12    | Analog grn video w/composite sync |    |       |       |       |
| 13    | Blue video ground                 | -> |       | 13    | 13    |
| 14    | Ground                            |    |       |       |       |
| 15    | NC                                |    |       |       |       |
| Shell | Earth ground                      | -> | Shell | Shell | Shell |

When Sense 0 (pin 4) is grounded, the card will generate a RS-343 video signal compatible with the Macintosh High-Resolution Monochrome and High-Resolution RGB monitor:

Horizontal Scanning = 35.000 KHz  
Dot Clock = 30.24 MHz  
Vertical Scanning = 66.67 Hz

When Sense 0 (pin 4) is not connected, the card will generate a RS-170 video signal compatible with the Apple II AppleColor RGB monitor:

Horizontal Scanning = 15.734 KHz  
Dot Clock = 12.27 Mhz  
Vertical Scanning = 60.0 Hz

In addition, the frame buffer size is reduced to fit the display area of the AppleColor RGB monitor.

(NOTE: This automatic sensing mechanism of the Apple High-Resolution Video card is similar to the Apple Portrait and Two-Page display cards, but does not have a shutdown mode -- that is, it does not show up in Control Panel -- when a monitor is not attached.

This feature is useful when you have two video cards installed, but only use one at a time. With the shutdown capability, the system software will recognize only the card with a monitor attached. Thus if a card is assigned the bootup monitor and the monitor is removed, the system will not send the startup video to a non-existent monitor.)

MacTCP: Where To Get Single-User And Site Licenses (9/95)

=====

Article Created: 25 November 1989  
Article Reviewed/Updated: 18 September 1995

TOPIC -----

I am interested in MacTCP. Does Apple offer any type of site licensing agreements, or is it sold on a cost-per-individual user basis?

DISCUSSION -----

MacTCP is available as a single-user and a site-licensed product. The single-use product is available with System 7.5, or if you do not have System 7.5, call 512-919-2645.

Customers interested in the site-licensed product need to contact Apple Computer Software Licensing. For more information, contact:

Apple Computer Software Licensing

## A/UX and X Windows: Frequently Asked Questions (12/95)

Revised: 12/1/95  
Security: Everyone

A/UX and X Windows: Frequently Asked Questions (12/95)

=====

Article Created: 26 November 1989  
Article Reviewed/Updated: 1 December 1995

TOPIC -----

This article contains frequently asked questions (FAQ) about A/UX and the X Window System.

DISCUSSION -----

Question: Does Apple provide a Motif Window Manager (mwm) to run under X Window System? Is there such manager available from a third-party? Are there any other window managers available under X Window System besides "twm", "uwm", and "wm"?

Answer: The Motif Window Manager (mwm) developed by OSF is available from Integrated Computer Solutions Inc.

There are also ports of OpenLook Window Manager "olwm" and Tom's Virtual twm "tvtwm" along with several others that run under A/UX.

Question: Is C++ available under A/UX yet? I thought I saw this recently, but I have not been able to find anything.

Answer: C++ is not available in A/UX; however, it is available through A/UX developer's tools from APDA. Also, the third-party product called "Designer C++" from Oasys, Inc. might have a solution for A/UX.

Question: Since Apple has announced MacX, will client applications written on the Macintosh OS be available as clients through MacX to other servers on an Ethernet? Can client applications be displayed on other X servers using MacX?

Answer: Currently, MacX acts as an X server that supports only X clients running on other machines, such as A/UX. No Macintosh client application can be run through MacX to other servers.

Question: How do you set the default for a color monitor when displaying the X Window System server? This can be done each time you run X by entering `-screen` and `-depth`, but is there a way to set the default to do this without entering these parameters?

Answer: Here are a couple of ways to do what you're looking to do:

- Create `.X11` file in users \$Home Directory, the file should contain a line reading:

```
/usr/bin/X11/X -screen 0 -depth 8
```

- You can create an alias in the `.login` or `.cshrc` file for this. For example:

```
alias Xcolor X /usr/bin/X11/X -screen 0 -depth 8
```

For more information, search under: "Integrated Computer Solutions" and "Oasys, Inc."

## SMB File Transfer: Using With OS/2 LAN Server

Revised: 12/13/89  
Security: Everyone

SMB File Transfer: Using With OS/2 LAN Server

=====

This article last reviewed: 25 November 1989

TOPIC -----

I have a large installation running PC LAN servers, and I want to connect via Apple's TokenTalk NB Card and use SMB File Transfer.

When I tried this , I got locked out because the installation had recently been upgraded to OS/2, which has additional privileges required by the OS/2 LAN server (LAN Manager).

I could see the directory on the server, but it wouldn't show any files. Can you give me any information on how to set privileges under an OS/2 LAN server that will allow the use of the TokenTalk NB Card and SMB File Transfer?

DISCUSSION -----

First off, when adding SMB File Transfer Utility users to the OS/2 server, remember to identify them as DOS users.

If no files or folders appear in the AFE window for any directory on an SMB server, there are three possible explanations:

- You have no access privileges for that directory.
- There are no files or folders for that directory.
- SMB File Transfer cannot determine your access privileges for the directory volume. If this is the case, SMB File Transfer assumes that you have no access privileges for this directory.

To determine access privileges when communicating with the OS/2 LAN server, SMB File Transfer requires that you have all privileges (A) for the directory to which you connect or, at least, one file exists in that directory.

If you do not have the required privileges, the network administrator must create at least one file in the directory to which users connect. This file will give SMB File Transfer the information it needs to determine your access privileges.

## Inter•Poll: Why Hop Count Fluctuates

Revised: 3/1/93  
Security: Everyone

Inter•Poll: Why Hop Count Fluctuates

=====

This article last reviewed: 25 November 1989

TOPIC -----

I am using Inter•Poll on my network. The network is all Macintosh systems connected with Farallon's PhoneNET.

I did an echo test and sent out 200 packets at an interval of 0. The hop count fluctuated between 2 and 3. Why?

DISCUSSION -----

The hop count tells you how many routers the packet had to go through to get to the destination node.

All routers maintain complete routing tables that allow them to determine how to forward a datagram (packet) on the basis of its destination network number. RTMP (Routing Table Maintenance Protocol) allows routers to exchange their routing tables periodically. In this process, a router receiving the routing table of another router compares and updates its own table to record the shortest path for each destination network. This exchange process allows the routers to respond to changes in the connectivity of the Internet (for example, when a router goes down or a router is installed).

During this process of exchange, routers sometimes lose track of the shortest path to a particular network, and the packet may go through one or more additional routers to reach its destination. This is not uncommon and is not normally anything to be concerned about.

## Laser Discs: Production Questions and Answers (11/95)

Revised: 11/21/95  
Security: Everyone

Laser Discs: Production Questions and Answers (11/95)

=====

Article Created: 13 December 1989  
Article Reviewed/Updated: 21 November 1995

TOPIC -----

This article contains some questions and answers about laser disc production.

DISCUSSION -----

Question: I have seen the "ABC News Presidential Election" laser disc. This particular disc has the single image (freeze frame) and runtime movie (video clips). I know about two methods of recording: CAV (still image) and CLV. Which method was used for this disc? Can you combine both methods of recording on one disc (one side with CAV and the other side with CLV)?

Answer: Constant Angular Velocity (CAV) is capable of providing both freeze-frame and full-motion video. Constant Linear Velocity can provide only the full motion video. Therefore, if both freeze frame and full motion are desired, then CAV is the technique to use when creating the laser disc.

The disadvantage of the CAV method concerns the amount of video that can be placed on the laser disc. This is 30 minutes per side. CAV plays only one frame in one revolution of the laser disc. This is where CLV has the advantage; it is capable of placing more video on the same disk, namely, 60 minutes per side. However, there are varying number of frames played during a revolution. This is why the freeze-frame feature is not available in the CLV format.

Technically, it would be feasible to use CAV on one side of a disc and CLV on the other side. Typically, this is not a method used in the laser disc industry since the CAV method provides both freeze frame and full motion.

Question: I would like to print my laser disc. I have all the materials on video tape. Can it be done?

Answer: Laser disc production houses have specifications that vary. Generally,

these production companies want the master video tape in the 1-inch broadcast tape format; some may accept 3/4-inch broadcast tape. There are precise specifications for the layout of information on these master video tapes. Different production companies may require slightly different layouts.

If material has been transferred from motion picture film to video tape, there are special considerations for freeze-frame images. The method of transfer from the film to the tape is very important. When transferring 24 frames a second (the film standard) to 30 frames a second (the NTSC video standard), the method used to compensate for the differing frame rates must be precisely controlled.

If the original material was shot on video tape, the frame-rate issue is not a concern. However, freeze-frame images still need special attention so there will not be image flicker during the laser disc freeze-frame display. Two methods are available: frame-accurate edits or multiple-frame recording.

- Frame-accurate edits allow just one frame of video to be recorded on the laser disc for the freeze-frame image. This is the preferred technique.

- Multiple-frame recording allows freeze frames without the need to have frame-accurate edits. Three frames are recorded on the laser disc, and the middle frame is used for the freeze frame. This uses space on the disc quickly; three times the space that is used for frame-accurate edits. Someone using a disc recorded with this method cannot step through the freeze frames, frame by frame, without seeing the same image three times.

Question: If I want my laser disc in NTSC format, what should I do?

- Will PAL-formatted video tapes work?
- Do I need high-band (broadcasting) or low-band (normal/home use) video tape?

Answer: It is possible to move from one format to the other, but there are issues that need to be addressed when using the CAV method. These are related to how the conversion takes place. A laser disc production company can explain the details of these issues.

Most disc production companies require the master video tape to be on 1-inch video tape or 3/4-inch video cassettes.

Question: How long does it take to do the pressing?

Answer: The usual turnaround -- from the time a production company receives the master video tape until the duplicated discs are ready -- is 10 days. If faster turnaround is required, turnaround time as short as same day is often available. However, any turnaround less than the typical 10 days will cost extra. The faster the turnaround, the more the cost.

In summary, using the CAV method requires a specifically formatted master video tape in 1-inch or 3/4-inch format. Freeze-frame images require very close attention to avoid image flicker. Film-to-video tape transfer is a very precise process that must be monitored very closely. Many laser disc

production companies provide books, at no cost, that detail the many specific issues that must be addressed to produce a quality video disc.

Macintosh IIci: Using Cache Memory Card (5/94)

=====

Article Created: 26 November 1989  
Article Reviewed/Updated: 23 May 1994

TOPIC -----

What is the maximum cache memory I can install in the Macintosh IIci?

DISCUSSION -----

The size of the Apple cache card for the Macintosh IIci is 32K. There is no real limit on the amount of memory a cache card designer can put on a cache card. The designer could cache the entire RAM address space of the computer, but beyond 32K, the improvement in performance per each 1K of cache memory diminishes greatly.

Performance tests indicate that the extremely marginal increase in speed gained by using 64K of cache memory is not worth the doubled static RAM cost. Beyond 64K, the speed improvement becomes almost nil.

The Macintosh IIci Cache Card part numbers are:

## SMB File Transfer: Extended Services & the NET SHARE Command

Revised: 12/13/89  
Security: Everyone

SMB File Transfer: Extended Services & the NET SHARE Command

=====

This article last reviewed: 2 November 1989

TOPIC -----

I have a small problem with the SMB File Transfer Utility using PC LAN 1.3 Extended Services.

Extended Services does not issue explicit NET SHARE commands when starting the LAN program. Instead, it does this within one of the .exe modules. When I try to connect to the SMB server, I get an "access denied" dialog (even though my user ID doesn't require a password). If I then issue a NET SHARE command on the PC to look at shared devices, I can see the devices that I defined as shared in Ext. Services Config. At this stage, I issue a NET SHARE command to reshare one of the devices, and I can access this without any problem. Why do I have to reshare a volume that my PC can already see?

DISCUSSION -----

We think you're making a fairly common mistake. The IBM manual describes a procedure for sharing filesets in such a way that the user may think it does the same function as NET SHARE. But this is not true! If you start Extended Services and then make the following menu choices: Administrator Services/PCLP/Adminsrv/Manage/filesets, you will be prompted to give information about the filesets that are to be shared. Doing a NET SHARE then shows a list of directories available to network users.

The procedure described above is unnecessary and can be eliminated. To work properly, the SMB file transfer software requires the NET SHARE command in the format: NET SHARE netName = DOSPathName

## Canon Color Laser 500: Driver Needed

Revised: 12/13/89  
Security: Everyone

Canon Color Laser 500: Driver Needed

=====

This article last reviewed: 2 November 1989

TOPIC -----

I heard that someone is developing a driver for Canon's Color Laser 500, which functions as a 400-dpi, 256-color scanner, hardcopy output device, and copier. Do you know of anyone who has a driver for it. (The interface is GPIB.)

DISCUSSION -----

As of September, 1989, neither we or Canon knew of any Macintosh printer or scanner drivers for the Canon Color Laser 500.

The General Purpose Interface Bus (GPIB) interface is defined by ANSI/IEEE Standard 488-1978. It is often referred to as the IEEE-488 bus, which is also synonymous with HP-IB. The GPIB is an 8-bit, parallel, digital bus with full handshake and interface management capabilities. It has been widely used for interfacing programmable instruments with computers.

You have many GPIB interfaces available to choose from for the Macintosh, whether it be for a Macintosh Plus, Macintosh IICx, and so on. Refer to any of the Macintosh buyer's guides for a listing of your options.

## Macintosh: Integrated Services Digital Networks (ISDN)

Revised: 7/23/92  
Security: Everyone

Macintosh: Integrated Services Digital Networks (ISDN)

=====

Article Created: 3 November 1989  
Article Last Reviewed: 10 August 1992  
Article Last Updated: 22 June 1992

TOPIC -----

Do you have information on Macintosh connectivity via Integrated Services Digital Networks (ISDN)?

DISCUSSION -----

Here is an introduction to ISDN and some interface possibilities.

ISDN

----

Integrated Services Digital Networks (ISDN) is a network architecture that uses digital technology to support integrated voice, data, and image services. It works through standard interfaces over standard twisted-pair telephone wire. The ISDN concept also includes some services not yet available, non-communications services, and services yet to be invented. Current work on ISDN standards is the responsibility of a number of study groups within the CCITT.

There are two types of ISDN channels: transparent and nontransparent. Transparent channels may carry whatever the user chooses--voice or high-speed data, for example--all independent of protocol. Non-transparent channels have been assigned specific protocols for specific functions on the network. The specified channels are:

B- (Bearer) A transparent digital channel of 64Kb, carrying circuit-mode or packet-mode user information (like voice, data, facsimile, and user-multiplexed information streams).

D- A non-transparent digital channel of 16 or 64Kb, used for signaling in association with one or more B-channels. This is also used for telemetry and

for low-speed packet-switched data.

H- (high-speed) Transparent digital channels, roughly equivalent to current T-carrier channels, for carrying circuit-mode or packet-mode user information--like multiplexed data, data and voice, or facsimile--at rates of millions of bits per second. Although H-channels have not been fully defined, an H0 channel operates at 384Kb; an H1 channel operates at 1536Kb (H11), or 1920Kb (H12). A H4 broadband version has been proposed that would operate at 135Mb.

Two other channels were once proposed, the A- and C-channels. These channels were intended to accommodate analog connections and related signaling. CCITT committees view such channels as obsolete. Nevertheless, analog-link interfaces are defined by CCITT, so during the duration that analog lines exist and continue to be used, they can interface to ISDN networks.

Although ISDNs are generally not yet a "tariff" service in most states (they are not priced by the California or equivalent Public Utilities Commissions), ISDN lines are readily available and acquired via contracts from the (in the US) Regional Bell Operating Company or AT&T. Most ISDN links are a combination of B-channels in association with a single D-channel for signaling. Signaling includes call establishment, call progress monitoring, call termination, and enhanced telephone features. The heaviest users may require one or more H-channels. Two standard service plans are expected to be offered:

- BRI: A Basic Rate Interface provides two transparent 64Kb B-channels and one nontransparent 16Kb D-channel per interface (2B+D). BRI provides two voice or data connections, or one voice and one data connection over the B-channels along with one or more low-speed, low-priority, packet-switched data or telemetry exchanges over the D-channel. The total data rate is 192Kb, with 144Kb available to users.
- PRI: A Primary Rate Interface provides 23 64Kb B-channels and one 64Kb D-channel (23B+D). This service is based on the U.S. T1 specification of 1.544Mb. The European PRI equivalent is based upon the CEPT specification of 2.048Mb, providing 30 B-channels and 1 D-channel (30B+D).

ISDN circuits are usable with Macintosh products. Generally speaking, there is FUNCTIONALLY no advantage to using ISDN over other links in today's analog or digital worlds (other than two circuit-switched devices per line, as opposed to one with analog). Therefore, when trying to decide whether ISN or ISDN solutions are best, consider what services you require.

AT&T and other manufacturers supply terminal adapters and CSU/DSUs that (with the proper hardware and software) let the Macintosh connect to ISDN circuits. Because terminal adapters and CSU/DSUs support certain switches, protocols, and interfaces, you need to ensure that the interfaces you plan to use are compatible with the ISDN circuit.

Among the various ways to interface a Macintosh to an ISDN network are:

- Using a Hayes-compatible terminal adapter (like Universal Data Systems TA100, Infotron Passport ISDN Terminal Adapters) with the software (like MacTerminal).
- Using the recently announced Solana H-server or other bridge (TeleBridge, R-Server, Ethernet bridges, and so on) with the appropriate CSU/DSU. These would provide a range of data rates, asynchronous or synchronous, 19.2 to 64Kb, or higher.

You can have terminal emulation with the first solution, whereas the second lets you create an AppleTalk or Ethernet Internet. Other solutions exist or will in the future.

#### DSU and CSU Units

-----

DSU stands for Data Service Unit, which is an interface to digital links. It is somewhat analogous to a "digital" modem. The DSUs translate the computer's unipolar serial data to baseband bipolar signals. The DSU uses a DCE interface to communicate with the terminal and then transmits the data in a special format over the link.

CSU (Channel Service Unit) is sometimes required at the end of some links. The trend today is to incorporate the CSU into the DSU.

For more information on manufacturers, check the Tech Info Library, under "Telebridge," "Universal Data," and "Infotron."

Editor's Note 22 June 1992: Solana has discontinued business to our knowledge, so we are unable to refer you to them directly for further information.

## GS/OS: How To See OS Info at Startup

Revised: 12/13/89  
Security: Everyone

GS/OS: How To See OS Info at Startup

=====

This article last reviewed: 3 November 1989

TOPIC -----

I have a lab of 16 Apple IIGS systems, running AppleShare 2.0.1 and the GS/OS 5.0 software with the Apple II setup from the GS/OS 5.0 disks. They are exhibiting some strange behavior when starting up over the network. When about half of the systems are started up, they get a list-type screen that says:

Welcome to the World of the Apple IIGS

and then a list of the network program segments that are loading. They get this instead of the Welcome to the Apple IIGS GRAPHIC SCREEN and the "thermometer".

DISCUSSION -----

The purpose of this screen is to provide operating system information to the operator. A list of installed GS/OS drivers is displayed as they are loaded.

This alternate screen is normal and is generated by pressing the space bar as GS/OS begins to load--whether starting up from a local disk or over the network. The screen will not appear unless someone presses the space bar sometime during the initial stages of booting the Apple IIGS.

If an Apple IIGS displays the alternate screen even when the space bar hasn't been pressed, there may be a hardware malfunction, and the unit should be serviced.

### TOPIC -----

This article gives sources for GKS (Graphic Kernel Systems) and PHIGS for A/UX.

### DISCUSSION -----

In the U.S., two companies have GKS and PHIGS: Prior Data Sciences and Advanced Technology Center.

Prior's GKS/C is a full implementation of the ANSI and ISO Graphical Kernel System (GKS) standard. It is a level 2c implementation, providing all graphic subroutine library output calls and request, sample, and event input. It is based on X11 as the screen/input handler with support for PostScript and other output devices. Prior has a GKS/PHIGS solution for A/UX.

Advanced Technology Center has GRAFPAK-GKS. GRAFPAK-GKS is a graphics subroutine library that conforms to the ANSI/ISO Graphical Kernel System (GKS). It provides comprehensive functions for developing graphics applications and includes the entire GKS functionality and extensions to the standard. Key features include levels 2b/2c implementation, distributed architecture, machine and device independence, Fortran and C language bindings (future support for ADA and Pascal), and extension to the Standard, Custom extension and porting is available.

In France, G5G has both GKS and PHIGS. SLX offers S GKS, an implementation

of the GKS standard for A/UX under X Window System.

For more details, search the Tech Info Library under "Prior Data," "Advanced Technology," "G5G," or "SLX."

## TSSnet 1.3.2: Incompatible with Macintosh IICI

Revised: 12/15/89  
Security: Everyone

TSSnet 1.3.2: Incompatible with Macintosh IICI

=====

This article last reviewed: 4 November 1989

TOPIC -----

I am running TokenTalk, EtherTalk, TSSnet, QuickMail 2.01 Server, and Apple Internet Router 2.0 all on the same machine (a Macintosh IICI). Despite my best efforts, TSSnet doesn't seem able to establish a communication channel with the VAX. Instead, it can see only the nearest DECnet router. However, it cannot speak to it (by terminal emulation, mail, file transfer, or otherwise).

DISCUSSION -----

We have isolated the problem. Do not run Alisa System's TSSnet 1.3.2 (or earlier) on the Macintosh IICI. Apparently, there seems to be some unknown problems in communication that can be duplicated in our office on our own VAX. We have successfully run TSSnet on a Macintosh II, Macintosh IIX, Macintosh IICX, and Macintosh II with a DayStar 33MHz accelerator card.

However, TSSnet on the Macintosh IICI does not operate, and will, in time, completely freeze the machine. As of October, 1989, Alisa Systems (and, consequently, Thursby Software, the authors of TSSnet) have been alerted, although a timetable for a fix is uncertain.

## AppleFax Modem 1.2: Upgrade and Compatibility Information 5/96

Revised: 5/30/96  
Security: Everyone

AppleFax Modem 1.2: Upgrade and Compatibility Information 5/96

=====

Article Created: 1 November 1989  
Article Reviewed/Updated: 30 May 1996

TOPIC -----

This article describes the AppleFax Modem Version 1.2 upgrade and how to get it. It covers the following topics:

- Upgrades: what you get
- How to get the upgrade
- Compatibility
- Tested products

DISCUSSION -----

Upgrades: What You Get

=====

The AppleFax Modem Version 1.2 upgrade consists of:

- 1) AppleFax software version 1.2 diskette, including:
  - AppleFax resource
  - AppleFax application
  - New "read me" file

Note: This software is incompatible with System 7 and higher and should not be used if you are using System 7 or higher.

- 2) AppleFax firmware version 1.2, a single ROM chip

All AppleFax Modems shipped after February 13, 1989 contain Version 1.2 of firmware ROMs and Version 1.2 of software.

## How to Get the Upgrade

=====

A no-charge upgrade for owners of previous AppleFax versions is available through the following channels:

### Firmware ROMs

-----

Version 1.2 of the firmware ROM (Apple part number 342-0387) has been available through AppleFax dealers as a no-charge service upgrade since November, 1988. AppleFax owners who have upgraded the firmware in their modems since November 1988 do not need to bring their modems in again.

This firmware ROM should be installed by an authorized Apple Servicing Dealer. We recommend against owners installing the ROM themselves.

### AppleFax Software

-----

Version 1.2 of AppleFax software is available to all authorized Apple Servicing Dealers. Dealers are free to distribute this software to their customers. The software is available on AppleLink and on other major, electronic-information services. Here is the path to find the software on AppleLink:

### Support

- Problem Resolution

- Tools & Utilities

- Apple Software Archives

- Peripheral Software

After obtaining the new software, a user should copy the new AppleFax resource into the System folder (replacing the previous version) and then copy the new AppleFax application program into the folder containing the previous version of the application (replacing it also). In addition, the "Read Me" file has been updated with new information on application and system compatibility.

### Compatibility

=====

The AppleFax Modem conforms to published CCITT Group 3 facsimile standards. In addition to adhering to these specifications, Apple has tested over 40 Group 3 facsimile machines from the major manufacturers of these devices over varying phone-line conditions.

While no significant problems remained during testing, Apple does not guarantee that AppleFax will always work with each fax machine due to phone line and equipment variations.

### Tested Products

=====

The following products have been tested with the AppleFax Modem:

- ALCATEL 3533
- CANON 220
- CANON 230
- CANON 320E
- CANON 510
- CANON FX 84
- DEX 370
- DEX 4200
- FOTOREX FAX 2000
- HARRIS/3M 2110
- HARRIS/3M 2127
- HARRIS/3M EMT 9140
- HARRIS/3M EMT 9145
- HARRIS/3M 9165
- HITACHI HIFAX 46
- HITACHI HF490
- INTERSCAN 7000
- KONIKA FAX 300
- MURATA F30
- MURATA F50
- MURATA IMAGE MATE
- NEC BIT 3
- NEC SYSTEM PF-1
- OKIFAX OF-10
- PANAFAX PX 100
- PANAFAX PX100A
- PANAFAX 400 AD
- PANAFAX UF 640
- PITNEY BOWES 8000
- PITNEY BOWES 8100
- PITNEY BOWES 8200
- RICOH RAPICOM 60
- RICOH RAPICOM 120
- RICOH RAPICOM 205
- RICOH RAPICOM 230
- RICOH RAPICOM 530
- RICOH RAPICOM 3300
- RICOH RAPICOM 5000
- SHARP FO-200
- SHARP FO-700
- SHARP FO-3100
- XEROX TELECOPIER 295

Article Change History:

30 May 1996 - Corrected minor typographical error.

28 Jun 1993 - Included AppleLink path. Noted software incompatibility with System 7 and higher.

## Macintosh: Calling Resources, MultiFinder, and Desktop Calls

Revised: 12/13/89  
Security: Everyone

Macintosh: Calling Resources, MultiFinder, and Desktop Calls

=====

This article last reviewed: 9 November 1989

TOPIC -----

I am programming in the Trader Workstation application. For my current project, I need to know if there is there a limit on the number of resources a program can call?

DISCUSSION -----

The theoretical limit on the number of resources an application can open at one time greatly exceeds the practical limits of a program. If you are not using "owned" resources, such as resources for desk accessories, you can have up to 32,767 of a single resource type. If each of those resources held 1Kb of data, you would be accessing on the order of 30MB. In other words, the limit on the number of resources you can have open at one time is not a real limit in the way that the limit on the number of open files is. If you are truly looking at having thousands of resources open at one time, you need to take a hard look at the way you are doing things and develop an alternative method for accessing data.

## System 6.0.2: Sound Manager Versus Sound Driver

Revised: 12/13/89  
Security: Everyone

System 6.0.2: Sound Manager Versus Sound Driver

=====

This article last reviewed: 9 November 1989

TOPIC -----

I need to find out about the Wave Table Synthesizer under the new Sound Manager. The Apple technical document states that the "synth" resource for the Wave Table Synthesizer in System 6.0.2 doesn't work with the Macintosh SE or Macintosh Plus. This is a big problem; I need to know when it will be fixed or a workaround that will be upwardly compatible--the beep generator just doesn't cut it, and I need four voices.

DISCUSSION -----

The fact that the Wave Table Synthesizer does not function on a Macintosh Plus or a Macintosh SE is a known limitation of the Sound Manager. This means that if you want a four-tone sound, you have to use the Sound Driver as opposed to the Sound Manager. Be aware that you cannot use both the Sound Driver and the Sound Manager at the same time, and, because SysBeep is owned by the Sound Manager, you cannot receive SysBeeps while using the Sound Driver.

A further note of caution: if you are going to use the Sound Driver this way, be sure to use System 6.0.4 or later. It solves a problem directly related to SysBeeps to prevent crashes caused by SysBeeps when you are using the Sound Driver.

## Empower: How to Decrypt Files

Revised: 12/13/89  
Security: Everyone

Empower: How to Decrypt Files

=====

This article last reviewed: 9 November 1989

TOPIC -----

I have been having problems with various HyperCard stacks giving me an "Old format" dialog while using Empower security software from Magna. I'd been having unusual system problems, so I trashed my System Folder, reinstalled new system software and reinstalled drivers and INITs. I did NOT reinstall the Empower INIT. Everything worked as though I'd never had Empower until I tried getting into those HyperCard stacks.

DISCUSSION -----

Using file encryption programs requires users to be careful: getting locked out is a common mistake. Denying access privileges to a folder causes Empower to encrypt files within it, and without Empower, they cannot be decrypted. This is what happened to the HyperCard files. If you compare a new stack with a problem stack under FEdit, you'll see the difference. If you check a few other files you had protected (including some non-HyperCard files), you'll find that they, too, still encrypted.

The fix is to restart with the Empower INIT installed, remove any volume protection (and all privileges) to decrypt any encrypted files, then remove Empower, and restart. After all security has been removed and files are no longer encrypted, all is normal.

Empower provides good security using a familiar interface, but can cause problems with careless use.

## EtherTalk and PacerLink: How They Can Delay Screen Echo

Revised: 12/13/89  
Security: Everyone

EtherTalk and PacerLink: How They Can Delay Screen Echo

=====

This article last reviewed: 15 November 1989

TOPIC -----

When using the following elements, I notice delays in screen echo:

- Apple EtherTalk card in a Macintosh II (2MB RAM)
- PacerLink (on Macintosh)
- Pacer (running on a DEC/VMS system)

For example, when typing data, I am forced to wait for the screen to show what was typed. The problem seems to be consistent, regardless of the number of users on the network or VAX. Likewise, the problem is consistent across all 23 Macintosh IIs.

However, the problem does NOT exist when using the Kinetics FastPath. The screen echo is consistent with the interactive mode the user expects. What's the problem?

DISCUSSION -----

We suspect that you are running into packet routing problems being caused by a remote AppleTalk bridge somewhere on the Ethernet. If there is a slower-speed link somewhere in the Ethernet (perhaps a 9600-baud link between remote sites), and, if that remote site has an AppleTalk bridge anywhere on it, you can get the situation you describe.

The problem arises because AppleTalk is treating the Ethernet as a single AppleTalk network, even though the Ethernet may consist of many networks in a complex setup. Because of this, the Macintoshes directly connected to the Ethernet use whichever bridge on this network was the last one to send an RTMP (Routing Table Maintenance Protocol) packet. Even though the VAX running Pacer software and the Macintoshes are on the same physical cable, a Macintosh cannot send its keystroke packets via that remote bridge, because it has no way of deciding which bridge is "closest" in terms of actual transmission time.

This does not happen when you put a Kinetics FastPath between the Macintoshes and the Ethernet, because the only bridge the Macintoshes get RTMP packets from is the FastPath, and it knows enough about the Ethernet to properly route the keystroke packets directly to the VAX.

One possible solution is to have the Ethernet bridges on the local side of the network refuse to transmit AppleTalk packets. If this is done, then the VAX running the Pacer Software once again begins acting as its own bridge for the Macintoshes directly connected to the Ethernet. The two packet types that you want the bridges to exclude are RTMP (Ethernet type 809b) and AARP (Ethernet type 80f3). You need to consult the documentation for your bridges for instructions on how the bridge excludes packet types from retransmission.

Be aware that stopping these packets from being transmitted over a bridge keeps you from using AppleTalk over the remote link.

## 4th Dimension 2.0.8: Needed for Macintosh IIci Compat. 12/89

Revised: 3/15/93  
Security: Everyone

4th Dimension 2.0.8: Needed for Macintosh IIci Compat. 12/89

=====

Article Created: 22 December 1989

TOPIC -----

This article discusses the incompatibility of early versions of 4th Dimension with the Macintosh IIci.

DISCUSSION -----

The international releases of 4th Dimension version 1.0.8 and earlier DO NOT run on a Macintosh IIci. The incompatibility stems from the copy protection method used in 4th Dimension's international releases.

4th Dimension v2.0.8 is the Macintosh IIci-compatible international release.

(NOTE: The United States releases of 4th Dimension all work properly on a Macintosh IIci.)

For information on how to upgrade to a new international Macintosh IIci-compatible version, contact the distributor of 4th Dimension in your country.

## FastPath 4: Problem and Fix

Revised: 12/22/89  
Security: Everyone

FastPath 4: Problem and Fix

=====

This article last reviewed: 12 December 1989

TOPIC -----

This article discusses a potential problem with Kinetics FastPath 4.

DISCUSSION -----

Here is a problem that may occur with Kinetics FastPath 4:

Symptoms:

- Affected FastPaths may reset at irregular intervals, resulting in a loss of network configuration and zones (i.e. the indicator lights on the front panel cycle continuously).
- On power up, the unit may not pass self-verification (i.e. all front panel indicator lights are on continuously).

Problem Description/Fix:

The DC power cable harness that connects the power supply to the main PRINTED CIRCUIT BOARD assembly may become loose, causing interference with the voltage regulation circuitry. To insure a consistent supply of voltage to the PRINTED CIRCUIT BOARD, the cable should be soldered to the power supply and PRINTED CIRCUIT BOARD.

All units manufactured since 1 October 1989 have this fix incorporated. The ECN (Engineering Change Notice) level has changed to #2446, Rev. N, which is stamped on the outside of the shipping box.

(NOTE: "Rev. J" still appears on the UNDERSIDE of the corrected FastPath unit.)

Solutions for units in the field:

## ..TIL04941-FastPath\_4-Problem\_and\_Fix\_(TA40721).pdf

Warranty rework is provided for FastPath 4s displaying the above symptoms.  
Please contact Novell Customer Service for help.

## Macintosh Portable: Can Use Square Wave Power Source

Revised: 7/30/92  
Security: Everyone

Macintosh Portable: Can Use Square Wave Power Source

=====

Article Created: 12 December 1989  
Article Last Reviewed: 30 July 1992  
Article Last Updated:

TOPIC -----

I want to use a Macintosh Portable on a boat. The boat generates a power source with a square wave as opposed to a sine wave.

Is it okay to use the Macintosh Portable on a square wave power supply?

DISCUSSION -----

The Macintosh Portable power adapter can be used in most voltage ranges and can accept a square wave from a generator. The power adapter has the following characteristics:

Input voltage: 85 to 270 VAC; 120/240 nominal  
Frequency: 48 to 62 Hz; 50/60 nominal  
Output current: 0.005 to 1.5 Amp maximum  
Output voltage: 7.5 +/- 0.1 VDC  
Operating temperature: 0 to 40 degrees centigrade (external temperature  
Weight: Less than one pound (varies depending on the unit)

## X Window: Colors (Bit Planes) Allowed

Revised: 2/11/93  
Security: Everyone

X Window: Colors (Bit Planes) Allowed

=====

Article Created: 12 December 1989

### Article Change History

-----

01/15/93 - REVIEWED  
• For technical accuracy.

### TOPIC -----

How many colors (bit planes) does the X Window specification allow? How many bit planes are supported by the MacX product?

### DISCUSSION -----

The X Window version X11 specification does not specify a maximum number of bit planes supported. The specification does say: "The number of bits in a pixel, and how a value translates into color, depends on the hardware."

The maximum number of bit planes that we have seen supported is 24. The MacX product supports 1- or 8-bit planes. The same applies to Apple's current X11 product under A/UX.

## GS/OS 5.0: No Finder Printing Fix

Revised: 12/22/89  
Security: Everyone

GS/OS 5.0: "No Finder" Printing Fix

=====

This article last reviewed: 12 December 1989

TOPIC -----

This article discusses a workaround for the problem of a GS/OS 5.0 startup disk without Finder, and its inability to retain default printer information.

DISCUSSION -----

The GS/OS 5.0 AppleShare startup disk without Finder is not capable of retaining default printer information. The startup printer selection made in the Apple II menu of AppleShare Administration is not used. Thus, if the disk is created as described in the manuals, the user must run the Chooser each time they restart the system to set a default printer.

Here is a workaround for this problem:

- 1) Copy the entire Chooser folder from the Apple IIGS workstation disk (or from the server) onto the startup disk. The file IWEM is not required if you are not printing to a LaserWriter.
- 2) Copy the file called ATINIT from the server onto the startup disk.
- 3) Set the Control Panel to either Scan or Startup Slot 5, then restart using this new disk.
- 4) Go into BASIC on the server, launch Chooser.II, and set the default printer settings. That printer will remain "selected" until someone runs Chooser.II to change it.
- 5) If you want the Chooser to be accessed from Aristotle, create an application that accesses the floppy disk copy of the Chooser, rather than the server-based version. The floppy disks must have a common volume name as well as pathname if this method is to be used.

## System 6: Sound Manager Issues

Revised: 12/22/89  
Security: Everyone

System 6: Sound Manager Issues

=====

This article last reviewed: 12 December 1989

TOPIC -----

The Macintosh II can handle "snd" and "snth" resources. System 6 notes suggest that the Macintosh Plus and Macintosh SE can do this too. Apart from the Macintosh II being stereo, what are the differences in sound play capabilities between the Macintosh SE and Macintosh II?

DISCUSSION -----

The question might be better stated: "What machines can use the Sound Manager?", since "snd" and "snth" resources are used by the Sound Manager.

Starting with the Macintosh Plus and continuing through the latest Macintosh, all can use the Sound Manager. However, the Macintosh Plus and the Macintosh SE have known difficulties with the Wave Table Synthesizer of the Sound Manager because of anomalies in the System Software. Basic Note Commands and Sampled Sound Synthesizer can be used from the Plus and the Macintosh SE.

The Macintosh II and later machines can use the Wave Table Synthesizer, the Basic Note Commands, and the Sampled Sound Synthesizer.

For more in-depth discussion of these issues, see the Inside Macintosh replacement chapter on the Sound Manager. This replacement chapter is posted on AppleLink. Follow this path to locate the document:

Developer Services:Macintosh Developer Technical Support:  
Interim Technical Documents:Sound Manager (Microsoft Word)

It's a Word 3.02 document which discusses the use of the Sound Manager in Macintosh Plus systems and later.

## TokenTalk NB Card: Incompatible with IBM ECF

Revised: 12/22/89  
Security: Everyone

TokenTalk NB Card: Incompatible with IBM ECF

=====

This article last reviewed: 12 December 1989

TOPIC -----

Does Apple's Token Ring card and MacDFT participate in what customers call IBM ECF (Enhanced Connectivity Facility)?

DISCUSSION -----

None of the software that Apple provides for the TokenTalk NB card supports ECF. ECF was one of the intermediate steps that IBM took towards SAA (Systems Application Architecture), and is no longer in the mainstream of architectures promoted by IBM except as a building block of SAA.

MacDFT uses our own proprietary API for communication with a host, and MacAPPC is fully compliant with IBM's LU 6.2 protocol specification (including the APPC verb set). Thus, Apple does not support the limited verb set specified by ECF (which is rarely used anyway).

## MPW 3.0: How To Build Header Files and Libraries

Revised: 12/22/89  
Security: Everyone

MPW 3.0: How To Build Header Files and Libraries

=====  
This article last reviewed: 12 December 1989

TOPIC -----

When converting from MPW C 2.0 to MPW C 3.0, I ran into the following problem.  
It seems the linker can't find some routines.

Have these been renamed or replaced? If so, the compiler accepted my calls  
since they appear in the #include files. I tried relinking with every library  
that shipped with MPW 3.0 and always got the same error.

Following is my link command and its output:

```
Link -w -t APPL -c Kran -sym on -mf C Option-D
... /* a bunch of my filenames */ Option-D
"{CLibraries}"CRuntime.o Option-D
"{Libraries}"Interface.o Option-D
"{Libraries}"DRVRRuntime.o Option-D
"{CLibraries}"StdCLib.o Option-D
"{CLibraries}"CSANELib.o Option-D
"{CLibraries}"Math.o Option-D
"{CLibraries}"CInterface.o Option-D
-o klink
setfile -a B klink
```

```
### Link: Error: Undefined entry, name: (Error 28) "KillIO"
Referenced from: setupSerComm in file: INIT.c.o
### Link: Error: Undefined entry, name: (Error 28) "OpenDriver"
Referenced from: setupSerComm in file: INIT.c.o
### Link: Error: Undefined entry, name: (Error 28) "RAMSDOpen"
Referenced from: setupSerComm in file: INIT.c.o
### Link: Error: Undefined entry, name: (Error 28) "FlushEvents"
Referenced from: main in file: main.c.o
### Link: Errors prevented normal completion.
### MPW Shell - Execution of input terminated.
```

DISCUSSION -----

We were able to successfully link a short C program that made all of these calls. We suspect that not all of the necessary files had been "included", which would definitely affect the way the linker operates. The following are the steps you can use to determine what header files and libraries are necessary for a complete build of your program:

- 1) With your directory set to the {MPW}Interfaces:CIncludes: folder, use the search command to search all of the header files for the routine you want to call. For example, we used the command:

```
search killio Option-X
```

where Option-X is the keystroke that generates the MPW wildcard character for filenames. This returned:

```
File "Devices.h"; Line 112 # Pascal OSErr KillIO(short refNum);
File "Devices.h"; Line 115 # Pascal OSErr PBKillIO(ParmBlkPtr
paramBlock, Boolean asynchronous);
File "Errors.h"; Line 32 # #define abortErr -27
                                /*IO call aborted by KillIO*/
File "Traps.h"; Line 597 # #define _KillIO
                                0xA006
```

Therefore, the header file that must be included is Devices.h.

- 2) Create a simple program that artificially calls the routines you want to use. In this case, we used:

```
#include <Types.h>
#include <OSEvents.h>
#include <Devices.h>
#include <Serial.h>
main()
{
    OSErr theResult;
    short *bogusRefNum;

    FlushEvents(0,0);
    theResult = KillIO(0);
    theResult = OpenDriver("\pbogus driver name",bogusRefNum);
    theResult = RamSDOpen(sPortA);
}
```

- 3) Use the Create Build Commands menu item from the Build menu to create a make file for your artificial program, and build the program to verify that it links properly.

(NOTE: Be sure you do not actually run the program since it is unlikely to run properly and, as in the case of our code, will crash.)

- 4) Open the make file generated, and you will have the necessary link command for the routines you wish to use. The make file generated for us follows:

```
# File:      testflush.make
# Target:    testflush
# Sources:   testflush.c
# Created:   Monday, November 13, 1989 3:20:14 PM
```

```
testflush.c.o Option-F testflush.make testflush.c
C testflush.c
```

```
SOURCES = testflush.c
OBJECTS = testflush.c.o
```

```
testflush Option-F testflush.make {OBJECTS}
Link -w -t APPL -c '????' Option-D
{OBJECTS} Option-D
"{CLibraries}"CRuntime.o Option-D
"{Libraries}"Interface.o Option-D
"{CLibraries}"StdCLib.o Option-D
"{CLibraries}"CSANELib.o Option-D
"{CLibraries}"Math.o Option-D
"{CLibraries}"CInterface.o Option-D
-o testflush
```

## Apple IIGS: Duplicate BASIC.SYSTEM Files

Revised: 12/22/89  
Security: Everyone

Apple IIGS: Duplicate BASIC.SYSTEM Files

=====

This article last reviewed: 12 December 1989

TOPIC -----

When using Apple IIGS System Installer 5.0 it appears to put the following files into the "Root" directory: BASIC.LAUNCHER, BASIC.SYSTEM, and ICONS.

The same file BASIC.SYSTEM is also in the folder called system. Do we need both? Are they there for Apple IIGS's diskless "boot up"?

DISCUSSION -----

Because you mentioned diskless booting, we assume you are talking about installing Apple IIGS/OS 5.0 on the Macintosh AppleShare File Server.

The only copies of BASIC.SYSTEM and BASIC.LAUNCHER that are installed by the Server Network Startup script are those installed at the root directory. The copy of BASIC.SYSTEM in the Macintosh System Folder is installed by the Apple II Setup installer when the server is set up for use by Apple IIs. A copy is put in the System Folder so that the server will have a default startup application for all Apple II users.

It is perfectly acceptable to remove the copy of BASIC.SYSTEM in the System Folder, so long as you remember to set a startup application for each Apple II user. You should not remove those copies of BASIC.SYSTEM and BASIC.LAUNCHER located at the root directory unless there is no need for Applesoft BASIC.

## AppleShare: How To Keep Apple II & Macintosh Software Separate

Revised: 12/22/89  
Security: Everyone

AppleShare: How To Keep Apple II & Macintosh Software Separate

=====

This article last reviewed: 12 December 1989

TOPIC -----

I want to use a utility (that is: Disk Tools, DiskTop or ResEdit) to make Apple II folders (that is: Aristotle, system, and users) invisible to Macintosh users. I want to prevent the users from going into a folder and trashing its contents. I could "lock" them, but if they don't know they are out there it works better in the long run.

Is this process safe?

DISCUSSION -----

The problem with making those files invisible to Macintosh users is that they will also be invisible to Apple IIGS users -- the Apple IIGS users will have no convenient way to launch Applesoft BASIC.

We recommend locking them. This prevents those without adequate AppleShare privileges from removing, renaming, or replacing them.

## HyperCard: Can't Simulate Mouse-Down In Other Applications

Revised: 6/24/90  
Security: Everyone

HyperCard: Can't Simulate Mouse-Down In Other Applications

=====

This article last reviewed: 14 December 1989

TOPIC -----

I use the following command in HyperCard with MultiFinder running:

```
open "filename1" with "Microsoft Word"
```

Microsoft Word launches and opens the document "filename1". I click on the HyperCard window to go back to HyperCard, then execute the following command:

```
open "filename2" with "Microsoft Word"
```

This time I go back to Microsoft Word, but it doesn't open the new file "filename2".

Can you explain this, and do you know if there is a workaround?

DISCUSSION -----

When running under MultiFinder, the HyperCard command:

```
open "filename" with "application"
```

behaves in one of two ways:

- 1) If the application is not open, HyperCard launches the application and passes the Finder the information needed to open the document "filename" to the application. This mechanism is documented on pages 55 and 56 of Inside Macintosh Volume II (included in master edition of Volumes I, II, and III, ISBN #0-201-17737-4).
- 2) If the application is already open, HyperCard brings the application window to the front. Since the application is already open, HyperCard

has no way to tell the application to open the document.

In System 6.0 and later, MultiFinder adds the ability to open documents from the Finder even though the application is already open. For example, if Microsoft Word is open with a document titled "filename1", and you switch to the Finder and double-click on a Microsoft Word document called "filename2", Microsoft Word opens this document. This happens because MultiFinder tricks Microsoft Word into opening the document by simulating a mouse-down event in the Microsoft Word menu item for opening files.

(NOTE: For a more complete description of this process, see the fourth paragraph on page 2 of Macintosh Technical Note #205.)

There is no workaround for the situation you describe. HyperCard, unlike MultiFinder, is unable simulate the mouse-down events in other applications.

## LaserWriter IINTX: Downloading PC Fonts To Hard Disk

Revised: 3/4/90  
Security: Everyone

LaserWriter IINTX: Downloading PC Fonts To Hard Disk

=====

This article last reviewed: 14 December 1989

TOPIC -----

I have several PCs and one LaserWriter IINTX. I will be using PostScript software on the PC.

How do I download PC fonts to a SCSI hard disk connected to the LaserWriter IINTX? Is there a special driver required? Does AppleShare PC include this option?

DISCUSSION -----

Adobe Systems provides software with their font library for the IBM PC and compatible computers that will download Type 1 PostScript fonts to the LaserWriter IINTX hard disk.

This is the only software we know of that will download Type 1 PostScript fonts to the LaserWriter IINTX hard disk. There is no way to download non-Type 1 PostScript fonts to the LaserWriter IINTX. An example of a non-Type 1 font would be any font created using third-party (not Adobe) font creation programs. We suggest you contact Adobe Systems, Inc. for more specific information.

For more information, search under: "Adobe"

## Macintosh Portable: How Battery Charge Affects Activity Status

Revised: 7/30/92  
Security: Everyone

Macintosh Portable: How Battery Charge Affects Activity Status

=====

Article Created: 14 December 1989  
Article Last Reviewed: 30 July 1992  
Article Last Updated:

TOPIC -----

If my portable is running from battery, and the system sleep time is set at 20 minutes (just for example), and I walk away with 15 minutes to go until the "reserve power" dialog appears, what will happen?

In 15 minutes, the dialog sleep warning appears. But, when a modal dialog such as the reserve power dialog is on the screen, when 5 more minutes have elapsed does a system sleep even occur, or will the machine actually drain all battery supplies if not attended?

What if my portable is running from battery and attached to an AppleTalk network? When the machine goes into a sleep voluntarily (set by me in the CDEV), the "I'm trying to sleep but I'm connected to a network" dialog appears and the machine never actually sleeps.

Aren't these potential battery-drain situations?

DISCUSSION -----

Here is a chart that shows what the Macintosh Portable is doing at various battery charge levels:

| Battery Voltage | Macintosh Portable Status                  |
|-----------------|--------------------------------------------|
| -----           | -----                                      |
| 7.2             | Charging with adapter                      |
| 6.4 - 6.0       | Battery without adapter (normal operation) |
| 5.9             | 1st software warning                       |
| 5.86            | 2nd software warning                       |
| 5.8             | 3rd software warning                       |
| 5.76            | 10 second warning                          |

|      |                   |
|------|-------------------|
| 5.72 | Software shutdown |
| 5.65 | Hardware shutdown |
| 5.4  | Battery sulfation |

Once the Macintosh Portable's battery reaches a voltage level 5.72 volts, the machine goes into software shutdown mode. This will occur regardless of the activity of the machine, even when connected to AppleTalk networks. This mode is equivalent to sleep mode except that the Macintosh Portable will not come out of software shutdown mode until the battery charger is plugged in or a battery with more than 5.8 volts is installed. Once in software shutdown mode, the Macintosh Portable will keep the contents of memory intact for about five days.

When the Macintosh Portable's battery reaches a voltage level 5.65 volts, the machine goes into hardware shutdown mode. This mode removes power from the entire system except for the Power Manager chip. All memory contents are lost. The Macintosh Portable will not come out of hardware shutdown mode until the battery charger is plugged in or a battery with more than 5.8 volts is installed.

## LaserWriter IINTX: Lots of Fonts on Hard Disk Slows Printing

Revised: 12/22/89  
Security: Everyone

LaserWriter IINTX: Lots of Fonts on Hard Disk Slows Printing

=====

This article last reviewed: 14 December 1989

TOPIC -----

I tried to set up my LaserWriter IINTX and a spare HD80 SC as a font cache. I've downloaded more than 400 PostScript fonts onto the HD80 SC.

Instead of getting an increase in the system throughput, I'm now experiencing delays approximately 5 to 6 times longer than before the hard disk was commissioned.

The utilities are current, and I'm using LaserWriter Driver 5.2, running under System 6.0.3. Do you have any suggestions as to why this problem has occurred?

DISCUSSION -----

According to the Addison-Wesley LaserWriter Reference Manual (ISBN #0-201-19258-6), Chapter 2, page 46:

"When the PostScript interpreter encounters the input /Palatino findfont, it first searches the FontDirectory (in memory), then searches the disk file system for the file named fonts/Palatino. If that search succeeds, PostScript executes the file, thereby loading it into virtual memory and registering the name Palatino in the FontDirectory."

Therefore, whenever the LaserWriter must find a font to use, it must search ALL available fonts -- starting from its own memory, then going to any attached hard disks -- to locate the proper font. It then must download it, as if from the system, for it to be available for use. With a directory of over 400 fonts, the search and download take a great deal of extra time.

## EtherTalk: How To Install Drivers

Revised: 12/22/89  
Security: Everyone

EtherTalk: How To Install Drivers

=====

This article last reviewed: 14 December 1989

TOPIC -----

As I understand it, Apple delivers EtherTalk 2.0 together with the EtherTalk NB Card.

Since EtherTalk 2.0 uses AppleTalk Phase 2, and not every networking and communication product can use AppleTalk Phase 2 -- GatorBox can't, for example -- what should I do if I still need to use EtherTalk 1.2 with the EtherTalk NB Card?

DISCUSSION -----

Apple now ships EtherTalk 2.0 software with all EtherTalk NB Cards. It is possible to install BOTH the EtherTalk 1.2 and EtherTalk 2.0 drivers on a Macintosh II, using the EtherTalk 2.0 Installer and a file on the EtherTalk 2.0 Installer Disk.

To install the EtherTalk 1.2 and EtherTalk 2.0 drivers, follow the installation sequence below:

- 1) Use the Installer on the EtherTalk 2.0 Installer Disk to install EtherTalk 2.0 on the destination Macintosh.
- 2) Open the folder called "Previous Version" on the EtherTalk 2.0 Installer Disk.
- 3) Copy the file "EtherTalk" to the System Folder of the destination Macintosh. This file is the EtherTalk 1.2 driver.

The System Folder of the destination Macintosh now contains both EtherTalk 1.2 and EtherTalk 2.0 drivers. Either one of these drivers may be selected via the "Network" CDEV. The EtherTalk 1.2 driver icon has a single arrow pointing to the left and right; the EtherTalk 2.0

driver has double arrows pointing to the left and right.

## Macintosh IIX: Lockup Caused By MIDI And SCC Chip Registers

Revised: 7/20/92  
Security: Everyone

Macintosh IIX: Lockup Caused By MIDI And SCC Chip Registers

Article Created: 19 December 1989  
Article Last Reviewed: 20 July 1992  
Article Last Updated:

TOPIC -----

System Configuration

-----  
Macintosh IIX  
Opcode Studio 3+ (MIDI interface)  
Opcode Vision (MIDI sequencer software)  
Digidesign SoundTools,  
System Software 6.0.3.

My Macintosh IIX sends a constant stream of data from the serial port.  
This affects the MIDI setup and creates a jam causing the MIDI devices and  
software to crash.

My first Macintosh IIX worked for a couple of days, then everything  
locked up. I returned it to the dealer and have the dealer's Macintosh IIX  
as a loaner, but that computer has the same problem.

DISCUSSION -----

This issue centers on the SCC chip power-on configuration and the fact  
that MIDI developers have had to bypass the Toolbox to write directly to  
the SCC chip. With MIDI Management Tools, Apple has provided the  
developers a MIDI toolbox to communicate to the serial ports without  
directly addressing the SCC chip. Since the MIDI Management Tools are a  
recent development, most existing MIDI programs still talk to the hardware  
directly.

Prior to Macintosh computers using the 68030, the contents of a  
particular register of the SCC chip had a power-on default of zero.

(NOTE: This one register will be the only one discussed, but there are other registers in the SCC.)

Starting with the Macintosh IIX, the register's power-on state may be set to something other than zero. This appears to be a random event. The Opcode utility (provided as a startup document, also known as an INIT) assures that the setting of the Macintosh SCC register is set to zero.

Some known sequences of events that reset the register of the SCC are:

- The Opcode INIT correctly sets the register's value at startup; printing takes place via a serial port; printing resets SCC register to something other than zero; SCC chip sends random data stream out the serial port; MIDI attempts to interpret the data stream as MIDI packets; everything connected to MIDI becomes confused (for example, locks up or crashes). Alternatively, nothing is sent out the serial port.
- AppleTalk, when it is turned on, changes the setting of the SCC register and sends AppleTalk packets; MIDI attempts to use those packets; this confuses all devices listening to the packets (for example, locks up or crashes). It is reported that Font/DA Juggler and Master Juggler are known to occasionally turn on AppleTalk.

To be sure that all works correctly, the following items need to be watched. These items assume that the Opcode INIT is in the System Folder of the startup disk.

- If any printing takes places after powering on and before a MIDI application is used, the SCC register may be in an incorrect setting for MIDI. Not printing prior to launching a MIDI program assures that the SCC's register configuration is proper.
- If AppleTalk is turned on before MIDI is used, the SCC registers are likely to change and, thus, may cause lockups to occur in MIDI devices. This includes: AppleTalk off at startup, turned on, turned off; or AppleTalk on at startup, then turned off. Restarting with AppleTalk inactive, and not activating AppleTalk prior to MIDI usage, should allow the MIDI session to run smoothly.
- (This is not verified but has some logical merit, so it may provide a workaround.) Launching MacTerminal and quitting has been reported to clear the lockups experienced on MIDI devices. This apparently sets the SCC's register to zero, which is the setting MIDI wants. One user with Southworth Music System's Jambox, a MIDI interface, uses the Jambox DA to clear the lockups. Both of these solutions seem to work due to their interaction with the SCC's register.
- It is also possible that a faulty SCC chip is on the logic board of the computer; however, with the situation appearing on two separate Macintosh IIX computers, it is unlikely that you are experiencing faulty hardware.

## System 6: Maximum Addressable RAM (9/93)

Revised: 9/2/93  
Security: Everyone

System 6: Maximum Addressable RAM (9/93)

Article Created: 22 December 1989  
Article Reviewed/Updated: 2 September 1993

TOPIC -----

What is the maximum addressable RAM for a Macintosh under System 6.0.7? We have a IIsi with 17MB of RAM installed (1MB on the main logic board plus four 4MB SIMMs), and the "About the Finder" shows 7MB available with the System using 10MB of RAM.

DISCUSSION -----

Macintosh system software version 6.0.x is currently unable to address any RAM above 8MB that is installed in the logic board SIMM sockets. The IIsi can detect and report the presence of a greater amount of RAM, but the operating system won't use it. The computer will behave as if it has 8MB of RAM. All the memory is available under A/UX or System 7.0.

System 6, when starting up, switches to 24-bit addressing mode and maps the installed RAM into an 8MB address space. Any RAM above 8MB is useless without a different operating system, A/UX being an example. The Macintosh knows that more RAM is installed but is unable to use it. You can verify that the RAM is recognized by selecting "About the Finder" from the Apple menu. It shows any RAM above 8MB as being added to the system memory.

Connectix Corporation has several products that take advantage of extra RAM under System 6:

- Optima makes System 6 32-bit clean and puts a Macintosh IIsi into 32-bit mode. This makes all of the physical RAM addressable by System 6. You can have one application open at a time.
- Maxima makes it possible to use up to 14MB of the RAM installed in a System 6-based system as RAM, with the excess RAM to be used as

a RAM Disk. You can have more than one application open at a time.

- Virtual 2.0 uses NuBus address ranges to add virtual memory above the 8MB boundary (up to 14MB). It uses the NuBus slot address ranges to extend the 8MB limit by mapping this larger space onto an equal-sized disk image. It then uses the Paged Memory Management Unit (PMMU) function of the 68030 (or 68020 with 68851 PMMU) to manage the swapping of required sections of this new, larger memory map to and from disk.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

## Macintosh: 286-Compatible Emulation Software Needed

Revised: 12/22/89  
Security: Everyone

Macintosh: 286-Compatible Emulation Software Needed

=====

This article last reviewed: 14 December 1989

TOPIC -----

I really need to be able to run an MS-DOS-based administration package inexpensively on my Macintosh.

The package is Dataflex v2.3 and although SoftPC will "sort of" run the installation section of the package, the package itself won't run at all. I assume that this is because SoftPC is an XT-compatible emulation. (It runs perfectly on the AST286 system.)

Are there any AT-compatible PC emulation packages that may get around the problem? I am trying to find a software solution to run on a Macintosh SE and to keep the cost to a minimum.

DISCUSSION -----

Apple Tech Comm is not aware of any PC emulation software other than SoftPC. The only 286-compatible solutions we know of are hardware-based solutions and the Mac286 product from Orange Micro (formerly from AST), which requires two NuBus slots.

It is possible to add a third-party NuBus expansion chassis to a Macintosh SE, but the cost is quite high. The combined price of an expansion chassis for the Macintosh SE and the Mac286 product makes this an unrealistic solution for a cost-conscious customer.

We recommend that you contact the vendor of the administration package to determine if they have an 8088-, 8086- or Macintosh-compatible version of their software.

AppleFax Modem: Distribution List Capacity (9/93)

=====

Article Created: 22 December 1989  
Article Reviewed/Updated: 2 September 1993

TOPIC -----

I want to send a single Fax through the AppleFax Modem to 300 different locations. What is the maximum number of addresses that the AppleFax software can send to in one batch?

DISCUSSION -----

The mechanism within the AppleFax application to send an envelope containing a document or documents to multiple addresses is called a Distribution List. The Distribution List has a theoretical limit of an integer, or approximately 32K names; however, you will run out of memory (and patience) long before that.

We have successfully sent over 100 addresses in a single Distribution List. We don't have any experience with larger quantities or the testing resources to check this, but we don't know of any reason why it wouldn't work with the proper amount of memory.

You might create many smaller Distribution Lists, or try one list and monitor memory consumption and add memory as appropriate.

Article Change History:

## MacDraw II: Scaling Discrepancy with LaserWriter Printing

Revised: 12/22/89  
Security: Everyone

MacDraw II: Scaling Discrepancy with LaserWriter Printing

=====

This article last reviewed: 19 December 1989

TOPIC -----

I have a problem using MacDraw II and a LaserWriter IISC (Printer Driver 1.1). When I try to print a line with a width of 0.5mm or smaller, lines with widths 0.5mm, 0.3mm, and 0.1mm print the same size.

The MacDraw II Reference Manual says that if your printer is a LaserWriter, for example, lines can be as small as 1/300 inch. Can you tell me what's causing my problem?

DISCUSSION -----

We tested MacDraw 1.0 and the latest release, MacDraw 1.1v2, on a LaserWriter IISC, LaserWriter IINTX, and LaserWriter Plus. Driver versions used included LaserWriter 5.2 and LaserWriter IISC 1.1. We used a Macintosh II and a Macintosh Plus running KanjiTalk 6.0.2.

We were able to scale a line to at least 0.1mm. Choosing anything smaller had no effect on the output. Though we could print all sizes to 0.1mm (for example, 0.5, 0.4, 0.3, 0.2, and 0.1) successfully, we were not able to print to 1/300 inch (0.083mm) as the MacDraw manual states.

CLARIS is aware of this scaling discrepancy in the LaserWriters output, and though they have a utility (available from CLARIS upon request) for improving the resolution of ImageWriter output, they have no solution for your problem as of December, 1989.

If you need the additional 0.017mm resolution, you should consider using another graphics program.

For more information, search under: "CLARIS"

## A/UX: Porting Applications from UNIX (8/94)

Revised: 8/24/94  
Security: Everyone

A/UX: Porting Applications from UNIX (8/94)

Article Created: 19 December 1989  
Article Reviewed/Updated: 23 August 1994

### TOPIC -----

I am a UNIX developer. I want to port one of my applications over to A/UX. Here are some questions:

- 1) Does A/UX use "TERMCAP" or "TERMINFO"?
- 2) The package compiles successfully on Convergent Technology's 68020 machine. Does this mean that there should be few problems on the A/UX?

### DISCUSSION -----

- 1) Both TERMCAP and TERMINFO (different formats of) terminal databases and libraries are supported by A/UX. The database file for the TERMCAP is the /etc/termcap file, and the database files for the TERMINFO are under the /usr/lib/terminfo directory.
- 2) A/UX is based on AT&T System V.2.2 UNIX with Berkeley software signals support. This allows most portable C code written on other UNIX machine, Convergent Technology's UNIX machine in this case, to be easily ported to A/UX without major modifications.

For A/UX third-party product information, search under the following AppleLink path:

## AppleShare PC 2.0: How To Access AppleTalk

Revised: 12/22/89  
Security: Everyone

AppleShare PC 2.0: How To Access AppleTalk

=====

This article last reviewed: 19 December 1989

TOPIC -----

How do I access from an MS-DOS machine the AppleTalk stack provided by AppleShare PC 2.0?

DISCUSSION -----

Use the same interface method as specified for AppleShare PC 1.2. This is documented in the APDA documentation for both AppleShare PC and the LocalTalk PC Card.

The reason the LocalTalk PC Card developer notes are relevant is that even though AppleShare PC 2.0 runs over multiple physical media, the API remains the same.

There is one important additional step that must be taken. Included with AppleShare PC 2.0 is a program called COMPAT.COM that installs a TSR (Terminate and Stay Resident) process. This process ensures compatibility between programs using the AppleShare PC 1.2 interface and AppleShare PC 2.0, and the program should be run at system startup.

## A/UX: How To Use With Apple Modem 2400

Revised: 9/24/92  
Security: Everyone

A/UX: How To Use With Apple Modem 2400

Article Created: 18 January 1990

### Article Change History

-----  
08/31/92 - REVIEWED  
o For technical accuracy.

### TOPIC -----

While testing the new prerelease Apple Modem 2400 with A/UX, I was unable to get it to function properly by using "getty" in the /etc/inittab. The modem answered the phone but never produced a tone. The phone hung up.

When I changed /etc/inittab to use "apm\_getty", the modem answered the phone and presented a tone, but it would connect at 1200 only -- not at 2400. Changing the apm\_getty parm to "at\_2400" did not solve the problem. This is the /etc/inittab entry that I am using:

```
00:2:respawn:/etc/apm_getty tty0 at_2400
```

Can you suggest something that would work with our new Apple Modem 2400 and allow it to operate at 300, 1200, or 2400 as determined by the speed of the incoming modem?

### DISCUSSION -----

We configured the Apple Modem 2400 for dial-in use with the standard getty. The apm\_getty operates only at 1200 baud. It is intended for use only with the 1200-baud Apple Personal Modem, which can't remember settings between resets.

Here are the steps we followed:

- 1) Connect the Apple Modem 2400 to the Macintosh modem port with cable (M0197, 590-0552). Turn on the modem.

2) Edit the file /usr/lib/uucp/L-devices to add this line:

```
DIR      tty0      tty0      2400
```

3) Open a connection to the modem using cu:

```
#cu -l tty0 -s2400      <- typed by you
Connected              <- returned by cu
```

4) Recall factory settings, change for dial-in use, and save the new settings:

```
AT&F                  <- typed by you
OK                   <- returned by modem
AT E0 Q1 &C0 &D2 S0=1 &W <- typed by you (0 is a zero)
                        <- nothing is returned because of our settings
```

5) Edit the file /etc/inittab to respawn a getty on tty0:

```
00:2:respawn:/etc/getty tty0 mo_2400
```

6) Edit /etc/gettydefs to limit rollover between 2400 and 300. Edit the mo\_2400 line to end with mo\_2400 instead of mo\_9600.

7) Start the getty process with INIT:

```
#INIT q
```

8) Dial in from another modem.

(NOTE: This configuration does not allow A/UX to sense a loss of the Carrier Detect signal -- that is, an accidental disconnection can result in the next caller getting the disconnected caller's login. Enabling this requires a different cable that connects the GPi line (pin 7) from the modem to the HSKi line (pin 2) of the Macintosh modem port. It also would require modifying the modem setup string (in step 4) to set &C1 instead of &C0.)

## Macintosh II Family: Internal Speaker Plays Left Channel Only

Revised: 7/2/92  
Security: Everyone

Macintosh II Family: Internal Speaker Plays Left Channel Only

=====

Article Created: 18 January 1990  
Article Last Reviewed: 25 June 1992  
Article Last Updated:

TOPIC -----

It seems that when a device is recorded in stereo (for example, from Farallon's MacRecorder), and you replay the sound through the built-in speaker on the Macintosh II, the computer combines both channels. On a Macintosh IICx, you hear only the left channel through the built-in speaker, even though the stereo port on both computers works correctly.

DISCUSSION -----

According to schematics, all Macintosh II products (Macintosh II, Macintosh IIX, Macintosh IICx, and Macintosh IICI) have only the left sound channel connected to the internal speaker.

(The Macintosh SE/30 has both sound channels connected to the internal speaker.)

If any users ARE actually getting stereo from any Macintosh II system, it has to do with software and not hardware. In all cases though, both channels are connected to the external speaker jack, so external speakers will produce correct stereo sound.

Apple Software: Where to Get Permission to Distribute (4/95)

=====

Article Created: 18 January 1990  
Article Reviewed/Updated: 14 April 1995

TOPIC -----

I am developing a Macintosh tutorial to be distributed on a CD-ROM. I want to know include the section of the Macintosh IIci and Macintosh SE/30 tour that has the user click on some numbers that turn into pigeons and fly off the screen.

Do I need Apple approval or copyright releases to distribute this? Is the tour engine Apple's, or is it licensed from a third party? Since I have purchased a copy with each Macintosh, can I load it onto a hard disk or other device (basically unaltered)?

DISCUSSION -----

Apple approval and licensing is required to distribute ANYTHING originally distributed on an Apple disk. This includes the tour engine you mentioned here, which is a heavily modified version of Interactive VideoWorks from MacroMind.

Send a letter to Apple Software Licensing explaining what you want to do and why. Software Licensing will evaluate the request. Apple's Software Licensing department licenses Apple software to independent software vendors for inclusion with their products.

For example, a vendor who publishes a word processing program with QuickTime capabilities may wish to include the QuickTime extension with the word processor. They would license QuickTime from Apple through this department.

## AppleTalk: Using Within a Token Ring Source Routing Environment

Revised: 3/4/90  
Security: Everyone

AppleTalk: Using Within a Token Ring Source Routing Environment

=====

This article last reviewed: 18 January 1990

TOPIC -----

Does the AppleTalk protocol running on the Token Ring board modify the optional source routing field within a Token Ring frame? If not, how does it resolve paths and routing to non-local networks?

Where can I get detailed information about the functions of AppleTalk within a Token Ring Source Routing environment?

DISCUSSION -----

Token Ring  
-----

The AppleTalk protocol layer does not directly modify the optional source routing fields in the 802.5 frame. Source routing in an 802.5 environment is handled by the LLC (Logical Link Control) layer within the TokenTalk NB Card (Macintoshes) in cooperation with source routing bridges. In the 802.5 world, the end nodes (Macintoshes) are responsible for determining how to route a packet to its destination and for caching and expiring that information for later use in route resolution. Each time a station needs to connect to an unknown host, it has to go through a route discovery process.

The discovery process involves sending a special packet (Discovery Packet) with an empty source routing field to all interconnected rings. This packet is sent across all source routing bridges to all nodes in the current ring environment. The first bridge encountered adds two network ID numbers, one for each of its connected networks, to the source routing field and forwards it on to the next ring. Each of following bridges adds one network ID to the source routing field up to a maximum of 7 networks. This is the maximum number of hops any one data packet can travel across. The node with the matching node ID responds to the discovery packet using the path contained within the discovery packet. This packet now provides the source station with the path to the remote node,

and also provides the remote node with the path to the source node. The discovery process is handled within the LLC and Macintosh layers of the TI TMS380 chip set. Support for source routing bridges is provided within the LLC and Macintosh layers of the TI TMS380 chip set. Support for source routing is provided for, but it's not automatic at the LLC layer. It's important to understand that the TI Token Ring chip set (the TMS380 family) fully implements the Macintosh and LLC layer services for the TokenTalk NB Card.

The TokenTalk NB Card also implements the SNAP (SubNetwork Access Protocol) for use with various protocol multiplexing and de-multiplexing functions. The AppleTalk protocol suite takes advantage of the SNAP protocol's implementation of automatic source routing support. The SNAP protocol allows support for building other layered protocols, which operate transparently in a source routing bridge environment.

Since we're using Token Ring, which provides its own 48-bit hardware address, we need to provide a mapping between the 802.5 address and the 8-bit AppleTalk node ID. The Macintosh uses the AppleTalk AARP protocol to accomplish this mapping. More information about AARP can be found in "Inside AppleTalk" (Addison Wesley, ISBN #0-201-19257-8).

#### Example

-----

A user on a Macintosh named "Pluto" (node ID 10) wants to mount a volume from an AppleShare File Server named "Bozo" (node ID 20) located on the other side of an IBM source routing bridge.

```
Ring 1          Ring 2
      Pluto%-----source routing bridge-----%Bozo
```

User pulls down the Chooser to locate the "Bozo" file server.

An NBP lookup is generated from Pluto, asking for all of the network-visible entities of type "AFPserver".

```
NBP(=:AFPserver:*)
```

This request is passed to the AppleTalk DDP layer as a broadcast to all AppleTalk nodes (address FF). The DDP layer uses AARP to determine that the AppleTalk address FF translates to the Token Ring address FFFFFFFF, the Token Ring broadcast address. Now that we have an 802.5 address, we can pass the address and data to the SNAP interface, which then passes it on to the LLC layer and finally out to the ring.

Each AppleShare File Server on all of the interconnected rings within the current zone would respond to the NBP lookup. The route to the file server would then be cached by the LLC layer; this allows us to resolve the node ID without the discovery process the next time we need to access this host. Now that we know the AppleTalk network number and node ID of the server, we can use them for any requests for services to the server.

As you can see, the AppleTalk protocols have no direct intervention with the source routing fields of the 802.5 frame. Source routing support is completely

handled from the LLC and Macintosh layers, and operates transparently to AppleTalk or any other protocol that uses the SNAP protocol interface.

More information about AARP can be found in "Inside AppleTalk" (Addison Wesley, ISBN #0-201-19257-8).

More information can be obtained about Token Ring (802.5) and source routing bridges in these materials:

## AppleShare: Limiting Users From Launching Applications

Revised: 3/4/90  
Security: Everyone

AppleShare: Limiting Users From Launching Applications

=====

This article last reviewed: 18 January 1990

TOPIC -----

I want to limit the number of users that can simultaneously launch applications on an AppleShare File Server. I am currently doing this on an IBM network.

- 1) Does the AppleTalk network system support the ability to limit the number of users who can simultaneously launch an application on a file server?
- 2) If this is possible, does it depend on the application software or the file server software?
- 3) If it depends on the application software, do you know of any applications that take advantage of this capability (particularly, productivity software, such as word processors and spreadsheets)?

DISCUSSION -----

AppleTalk Filing Protocol (AFP) does not directly support the ability to limit the number of users launching an application. This is something the developer of the application must provide within their code. AFP does provide methods to allow a developer to accomplish this type of limiting. For a more detailed discussion of multilaunch applications, review "Software Applications in a Shared Environment", available from APDA, part number A7Z0014.

Microsoft Technical Support indicates that Microsoft Word, versions 3.0.x and 4.0; Microsoft Excel, versions 1.5 and 2.2; Microsoft File 2.0 and PowerPoint, versions 1.0 and 2.0 are all multilaunch applications. Each has some limited multi-user capabilities as well.

## Apple Internet Router: Timbuktu & Macintosh II Incompatibility

Revised: 3/4/90  
Security: Everyone

Apple Internet Router: Timbuktu & Macintosh II Incompatibility

=====

This article last reviewed: 29 January 1990

TOPIC -----

This article discusses a compatibility problem between the Apple Internet Router, Timbuktu 3.x, and members of the Macintosh II family running with more than 1-bit color

DISCUSSION -----

There is a compatibility problem between the Apple Internet Router, Timbuktu 3.x, and members of the Macintosh II family running with more than 1-bit color.

To reproduce the problem, put an Apple Internet Router on a Macintosh II and set the Monitors CDEV to anything other than two-color black and white. When Timbuktu makes a connection with the router system, the screen on both the router system and the observing system become mangled. The text in the Port Statistics window changes size and moves to a different place on the screen. In the Network Information window, a dark black line appears on the top third of the screen.

The workaround is to set the router system to 1-bit color. It is possible to adjust the router system without restarting or breaking the Timbuktu connection.

Farallon, manufacturer of Timbuktu, says that Timbuktu should be used only in two-color, black and white mode.

## Apple IIGS: Don't Use DuoDisk on SmartPort

Revised: 3/4/90  
Security: Everyone

Apple IIGS: Don't Use DuoDisk on SmartPort

=====

This article last reviewed: 5 February 1990

TOPIC -----

I am experiencing a problem using DuoDisk with the Apple IIGS.

Equipment  
-----

"Blockbuster" Apple IIGS with Rev. 3.0 ROM, DuoDisk, Profile or SCSI HDA in slot 7 (optional)

Reproducing the Problem  
-----

Plug the DuoDisk into the disk port on the Apple IIGS main logic board. Install the ProFile in slot 7, and set the Control Panel to "your card." Leave both DuoDisk drives empty and power on the system. Set startup to "Scan."

The DuoDisk LED for drive #1 should turn on, but the system will not start. Why did the Apple IIGS skip the ProFile in slot 7? Now, power down the Apple IIGS and put a non-write-protected disk in the DuoDisk drive. It still doesn't start.

Power down the Apple IIGS and place a write-protected disk in the drive. Power on the system. The system starts up as expected, following the "Control Panel".

If the system appears to be "hung" following any of the above steps, momentarily triggering the write-protect switch by inserting anything into the drive allows the system to start up.

There appears to be a compatibility problem with the new Apple IIGS main logic board and the DuoDisk. Performing the "DuoDisk/Apple IIGS fix" that is posted on AppleLink has no effect since the problem appears to be hardware (firmware)

based.

I'm stumped. What's going on?

DISCUSSION -----

Tech Comm was able to reproduce this problem exactly as you describe.

There IS a compatibility problem with the DuoDisk and the Rev 3 Apple IIGS main logic board.

A check with Engineering provided us with the only workaround. Do NOT use the DuoDisk on the SmartPort. There is some code in the ROM that does not handle the interface to a DuoDisk properly. As of February, 1990, the only workaround is to use the DuoDisk on an interface card.

## No-hands Input Devices for the Handicapped

Revised: 3/4/90  
Security: Everyone

No-hands Input Devices for the Handicapped

=====

This article last reviewed: 5 February 1990

TOPIC -----

This article discusses "no-hands" input devices for profoundly handicapped computer users.

DISCUSSION -----

A popular device for profoundly handicapped users is the Headmaster by Personics Corp., which mounts on the head with a headband. Depending on head position, the position of the cursor can be controlled on the screen, and the equivalent of a mouse click is generated using one of several other devices.

The package also includes a special DA that puts a soft keyboard on the screen that runs concurrently with other applications, such as Microsoft Word. By selecting letters on the keyboard and generating a mouse click, characters are entered into the application. (Selecting commands from the pull-down menus is straightforward when using the Headmaster to control the cursor and the mouse-click device.)

The Headmaster unit has also been tested with the Macintosh Portable, and it works fine.

## InitCdev 2.0: Using with Virus Detectors May Cause Problems

Revised: 3/4/90  
Security: Everyone

InitCdev 2.0: Using with Virus Detectors May Cause Problems

=====

This article last reviewed: 5 February 1990

TOPIC -----

I've been using InitCdev 2.0, a freeware INIT management utility. Today, I installed the AppleComm Toolbox on my system.

When I invoke InitCdev, it crashes with ID=17 (package 0 not present--list manager). Can you explain?

DISCUSSION -----

Your problem may be the order in which your INITS are loaded.

We tested the InitCdev with the Toolbox. After moving a couple of virus detectors around, so that SAM Intercept loads BEFORE the InitCdev, and Vaccine loads AFTER InitCdev, the Apple Communication Toolbox worked great.

Some virus detectors don't respond well to the way this INIT manipulates them.

## HyperCard: Card Name Limitation

Revised: 3/4/90  
Security: Everyone

HyperCard: Card Name Limitation

=====

Article Created: 5 February 1990  
Article Last Reviewed: 27 July 1992  
Article Last Updated: 27 July 1992

TOPIC -----

While working on a HyperCard stack, I entered a card name that contained 29 characters. From any card, I could type "go to [card name]" in the message box or from a script, and go to that card. If I changed the name of that card to a 34-character name and made the appropriate changes in my script or the message box, I get a message "String too long."

I can type much more than 29 characters in the name of that card, but is there a HyperCard limit on the card name length?

DISCUSSION -----

Official HyperCard documentation states that HyperCard (up through version 2.1) will read up to 31 characters as a valid parameter when you use the GO HyperTalk command or a script to address a card by name. This is the theoretical limit, though tests show that HyperCard accepts 33-character names as a valid practical limit. Bigger and more complex stacks could pull the practical limit more in line with the theoretical. In tests, entering a card name of 34 or longer gives the message "String too long."

The 31 character limit concerns accessing the card, not simply naming it. You can type as many characters as you want into the Card Name area of the Card Info dialog box, but for obvious reasons this is not advised. You would not be able to access the card directly with a name over the maximum valid number above.

HyperCard 1.2.5: Disks Are Mislabelled as "1.2.3"

=====

This article last reviewed: 5 February 1990

TOPIC -----

This article contains information about HyperCard version 1.2.5, which has been mis-labeled in some situations as v1.2.3.

DISCUSSION -----

Some users are buying Macintoshes and getting disks labeled HyperCard version 1.2.3 -- although the "About" box shows version 1.2.5.

HyperCard version 1.2.3 was an internal testing version and never distributed to the general public as a product.

Despite what may be listed in some publications, the CORRECT HyperCard version for use with the Macintosh Portable and Macintosh IIci, under System Software 6.0.4, is HyperCard version 1.2.5.

## AppleShare: How To Correctly Shut Down Remotely

Revised: 3/4/90  
Security: Everyone

AppleShare: How To Correctly Shut Down Remotely

=====

This article last reviewed: 5 February 1990

TOPIC -----

What happens when a foreground application (or possibly a DA) issues a Shutdown command to the Macintosh while it is running the AppleShare File Server software? Will any damage be done to open files, or does the Shutdown process force AppleShare to clean all of its active and idle open file services before shutting down?

I want to perform a remote restart of the system to activate some system updates that take place only at startup. I am concerned about what that might do to the file server operation, since I'm not using the Shutdown option under on the AppleShare menu.

DISCUSSION -----

The only correct way to shut down the AppleShare File Server software is by using the Shutdown option under the AppleShare menu. Choosing Shutdown from the Special menu or executing a shutdown trap does not guarantee that anything currently in the AppleShare's buffers will be written to disk before the shutdown occurs.

The only way we know of to control AppleShare remotely is by using Timbuktu/Remote from Farallon Computing, Inc.

## LaserWriter Driver 6.0: Palatino Bold Print Size Problem

Revised: 11/5/91  
Security: Everyone

LaserWriter Driver 6.0: Palatino Bold Print Size Problem

=====

Article Created: 4 March 1990  
Article Last Reviewed: 5 November 1991  
Article Last Updated: 5 November 1991

TOPIC -----

I am using PageMaker 3.02 and LaserWriter Driver 6.0.

When printing Palatino Bold, the printed character appears to print one point smaller: a line of 9-point Plain text looks a little bigger than 9-point Bold text in Palatino. It's really noticeable when printing numbers.

This happens whether you use the Apple driver or the Aldus driver. I tried this in Microsoft Word 4.0, and it happens there as well. Can you explain?

DISCUSSION -----

We were able to duplicate the problem you describe and found that Palatino Bold prints about one dot (not point size), or about 1/300 inch, smaller than the Plain text Palatino. This is the result of the PostScript definition of the font and is independent of application or driver.

This can be fixed only with a change to the ROM.

The only solution with this combination of PageMaker and the LaserWriter Driver, is to use a different font family.

Internet Router: Compatible with LatticeNet Products

=====

This article last reviewed: 5 February 1990

TOPIC -----

Can LatticeNet be used with the AppleTalk Internet Router? Are there any support issue to be considered?

DISCUSSION -----

Apple has been using the Synoptics LatticeNet products with the Apple EtherTalk Interface Card and the AppleTalk Internet Router with no problems.

We can think of no unique support issues that the AppleTalk Internet Router would add to a LatticeNet network.

## Apple IIe: Network Printing Problem

Revised: 3/4/90  
Security: Everyone

Apple IIe: Network Printing Problem

=====

This article last reviewed: 5 February 1990

TOPIC -----

I am working with a school which has a lab of 14 Apple IIe systems sharing two network ImageWriters with no file server.

They have been unable to get the Apple IIe systems to print from any application, so I was brought into the situation. I moved the Workstation Card to slot 1, used Chooser.II, and was able to get all their software to print over the network.

The interesting thing is that the printer would work only by placing the LocalTalk connector in the serial printer port rather than LocalTalk port on the Workstation Card. The Chooser finds the printer as a network printer.

Can you explain?

DISCUSSION -----

It sounds as though the cables from the adapter box have been reversed during installation.

The top cable (LocalTalk) from the adapter box needs to be attached to the top connector pins on the Workstation Card. The bottom cable (printer port) from the adapter box needs to be attached to the bottom connector pins. If the cables from the adapter box to the Workstation Card have been reversed, the situation you describe would occur.

Once you were able to see the network from slot 1, did you try using slot 7 again? Were you able to see the network (even with the LocalTalk connector in the printer port)? Were you able to print from the applications?

Since you were able to see the network (that is, with Chooser.II), yet could not print, our first suggestion would be to check the printer slot assignment

in the application. The application needs to be set to print to slot 7 if the Workstation Card is in slot 7.

## TokenTalk 2.0 Installer: Problem and Fix

Revised: 3/4/90  
Security: Everyone

TokenTalk 2.0 Installer: Problem and Fix

=====

This article last reviewed: 5 February 1990

TOPIC -----

This article discusses how to spot and fix incorrect TokenTalk 2.0 Installer disks.

DISCUSSION -----

I was installing some Macintosh IIs on a Token Ring network and discovered a problem with the TokenTalk 2.0 Installer disks that are shipping with the TokenTalk NB Card.

The TokenTalk 2.0 disk (Apple Part #690-5435-A) included with the cards is not configured properly for the System 6.0.4 Network Products Installer disk.

The released disk is named "Token Talk Installer" (there is a space between 'Token' and 'Talk') instead of "TokenTalk Installer", and this prevents the MultiDisk Installer from recognizing this disk. In addition, all of the files on the released disk are inside a folder called "TokenTalk Installer" (which should be the name of the disk). The proper files/folders are within this folder -- that is, Installer, Installer Scripts, and System Folder.

To recap: the hierarchy of the released disk:

Disk Name: "Token Talk Installer"  
1st Window contains: "TokenTalk Installer" folder  
This folder contains: "Installer"  
                          "Installer Scripts"  
                          "System Folder"

Valid disks have this hierarchy:

Disk Name: "TokenTalk Installer"  
1st Window contains: "Installer"

"Installer Scripts"

"System Folder"

Renaming the released disk to the proper name (that is, removing the space) and then moving the Installer, Scripts, and System Folder to the main/root window makes this disk usable with the MultiDisk Installer.

(NOTE: As of February, 1990, Apple Manufacturing is aware of the mistake and has corrected it, so there shouldn't be many more of these disks sent out.)

## Line Printers for LocalTalk-Based Network

Revised: 7/23/92  
Security: Everyone

Line Printers for LocalTalk-Based Network

=====  
Article Created: 4 March 1990  
Article Last Reviewed: 7 February 1990  
Article Last Updated: 22 June 1992

TOPIC -----

I need a high-speed line printer that can connect to a Macintosh network (LocalTalk-based) for times when PostScript isn't necessary. I currently have an IBM 3262 and IBM 5262 printer that I would like to use, but I'm willing to buy another model or brand, if necessary.

Can IrmaPrint handle these models?

DISCUSSION -----

The IBM 3262 printer can be directly attached to the 5360 System Unit as the system printer. This means that it is a System 36 printer -- and, because it can be directly attached, it is most likely a Twinax connection. There is no method for connecting this printer to a LocalTalk-based network.

The IBM 5262 printer is a freestanding line printer also associated with the System 36. It may have RS-232 interconnection available. If so, the following scenario would be applicable.

(NOTE: A Check with DCA revealed that neither of the mentioned printers is supported by IrmaPrint.)

At Tech Comm we have used a Printronix Model 300XG line printer with a Centronics parallel interface. We connected it to a Macintosh II via a Tigertronics Model 770 serial-to-parallel converter. The Typewriter driver from the Microsoft Word 1.05 disk was moved into the System Folder, selected from the Chooser, and set up for 9600-baud and 10-pitch. A 23-page document was created and successfully printed via the Typewriter driver to the Printronix.

One current method of connecting this type of printer to the network is from Orange Micro, called Orange Port. It looks like a Solana R-Server and allows connection of serial devices to an AppleTalk network.

Solana Electronics also markets devices that are designed to connect non-networkable printers to AppleTalk networks. If the printers are serial, either the R-Server, the X810.1, or X810.2 could be used. If the printer is parallel, then the X810.2 is necessary. The X8120 devices can be set up with up to 2MB of memory to be used as data buffer, store and forward messages, and so on.

While we know this scenario functions properly, any serial-to-parallel converter should work, and if the printer in question already has a serial connection, only network-to-serial conversion would be necessary.

For more information, search under: "Orange Micro"

Editor's Note 22 June 199: Solana has discontinued business to our knowledge, so we are unable to refer you to them directly for further information.

## LaserWriter: Setting Manual Feed Through PostScript (2/95)

Revised: 2/22/95  
Security: Everyone

LaserWriter: Setting Manual Feed Through PostScript (2/95)

Article Created: 7 February 1990  
Article Reviewed/Updated: 22 February 1995

TOPIC -----

I have a DayStar Digital board and need the PostScript code necessary to set up the LaserWriter for Manual Feed.

DISCUSSION -----

According to the PostScript Language Reference Manual (ISBN #0-201-10174-2), Appendix D, Page 303:

"statusdict contains two operators (setjobtimeout and jobtimeout) with immediate effects that do not persist from one job to the next. The remaining statusdict entries are not operators but ordinary data values such as Boolean, integers, and strings. They may be read and written in the usual way by PostScript dictionary operators, such as get and put. There are no restrictions on changing these parameters; the effects of changes persist only until the end of the current job.

There are several additional statusdict entries that are not documented. They have to do with the operation of the server and are not intended for execution by users programs."

The statusdict entry is "manualfeed", which is a Boolean that controls whether the paper is to be fed manually (true) or from the paper tray (false)."

The syntax is basically the same as the AppleTalk-type changes you have seen previously.

Caution:  
-----

If you choose to use the PostScript code provided in this article, you assume all risks involved in making these changes. PostScript code, if not entered correctly, can place the LaserWriter into a condition requiring service.

```
%=====
% Begin PostScript Code
%
serverdict begin 0 exitserver
statusdict begin
currentdict manualfeed true put
end
%
% Begin PostScript Code
%=====
```

Remember, these "volatile parameters" persist only until the end of the current job. Any volatile parameter(s) changed must be set to their desired values prior to printing and will revert to their default values after the print job is completed. Setting these parameters is accomplished by prepending the above short program to any text file sent to the LaserWriter, or by sending the program before sending any other PostScript file.

## Macintosh II: Baud Rate Settings

Revised: 12/17/91  
Security: Everyone

Macintosh II: Baud Rate Settings

=====  
Article Created: 7 February 1990  
Article Last Reviewed: 10 August 1992  
Article Last Updated:

TOPIC -----

My Macintosh II systems interface to Opto-22 digital and analog I/O modules via the modem port. The Opto-22 is capable of serial communications at speeds up to 38.4 kilobaud. At this time, I'm using 19.2 kilobaud, but I would very much like to communicate over the modem port at 38.4 kilobaud. According to "Inside Macintosh Vol II," this baud rate is unsupported. Can you explain?

I heard that a baud rate code of 1, 2, or 3 might allow talking at 38.4 kilobaud. Is this true?

DISCUSSION -----

"Inside Macintosh, Volume II" (Addison Wesley, ISBN #0-201-17737-4) does NOT state that 38.4K is not supported in hardware. It DOES show that a predefined constant has not been created for the speed.

In other words, the constant "baud38400 = 1" is not part of the serial driver's implementation. This is not indicative of the serial driver's capabilities. By setting a serConfig to the correct value and using the SerReset function, the serial driver is able to use the 38.4K speed. Developer Support indicates that the correct value for 38.4K speed is 1.

The values of the various speeds are derived from the way bits are set in the serConfig variable of the SerReset function (discussed on page II-250 of Inside Macintosh). A table representing these variables looks like this:

| Bits: |    |    |    |   |   |   |   | Actual | Baud | Constant |
|-------|----|----|----|---|---|---|---|--------|------|----------|
|       | 64 | 32 | 16 | 8 | 4 | 2 | 1 | Value  | Rate | Name     |

| -- | -- | -- | -- | -- | -- | -- | ----- | -----   | -----     |
|----|----|----|----|----|----|----|-------|---------|-----------|
| 0  | 0  | 0  | 0  | 0  | 0  | 0  | = 0   | = 57600 | baud57600 |
| 0  | 0  | 0  | 0  | 0  | 0  | 1  | = 1   | = 38400 |           |
| 0  | 0  | 0  | 0  | 1  | 0  | 0  | = 4   | = 19200 | baud19200 |
| 0  | 0  | 0  | 1  | 0  | 1  | 0  | = 10  | = 9600  | baud9600  |
| 0  | 0  | 0  | 1  | 1  | 1  | 0  | = 14  | = 7200  | baud7200  |
| 0  | 0  | 1  | 0  | 1  | 1  | 0  | = 22  | = 4800  | baud4800  |
| 0  | 0  | 1  | 1  | 1  | 1  | 0  | = 30  | = 3600  | baud3600  |
| 0  | 1  | 0  | 1  | 1  | 1  | 0  | = 46  | = 2400  | baud2400  |
| 0  | 1  | 1  | 1  | 1  | 1  | 0  | = 62  | = 1800  | baud1800  |
| 1  | 0  | 1  | 1  | 1  | 1  | 0  | = 94  | = 1200  | baud1200  |

## Macintosh: International System Software Differences

Revised: 5/16/91  
Security: Everyone

Macintosh: International System Software Differences

=====

This article last reviewed: 7 February 1990

TOPIC -----

What are the differences between the U.S. and International versions of System Software 6.0.3?

I'm doing a 12-country rollout of an application I wrote, and may be running international versions of the System Software at those sites (for instance, using B 6.0.3 in London).

Are there any differences that may affect the application I have written in Think C?

DISCUSSION -----

Keyboard layouts, sort orders, paper size, and unit defaults are among the things that might be different between System Software versions.

Inside Macintosh, Volume I, Chapter 19, and Volume 5, Chapter 16 (available in omnibus edition from Addison Wesley, ISBN #0-201-17737-4) discusses the International Utilities Package that allows software developers to make their software country-independent.

Everything you need to know about localization should be contained in these documents.

## WDEF Virus: May Cause AppleShare Performance Problems

Revised: 3/4/90  
Security: Everyone

WDEF Virus: May Cause AppleShare Performance Problems

=====

This article last reviewed: 7 February 1990

TOPIC -----

Over the past 2 weeks, some of my AppleShare workstations are sporadically slowing down.

When a server volume is mounted and the mouse is moved, the pointer changes to a watch, and the AppleTalk arrows activate. Trashing the server volume makes the problem go away.

These workstations are Macintosh II and Macintosh Plus Systems running System Software 6.0.2 and using AppleShare 2.0.1.

I also have a question regarding a network problem.

I have a six-system network on PhoneNET cabling, with one Macintosh SE/30 as an AppleShare server. After using the one Macintosh IICx for about a minute, it freezes, and the server activity bar just bounces back and forth for several minutes. I connected only the Macintosh IICx to the Macintosh SE/30 to lessen the problem, but it is still there. I've replaced the connectors on both machines.

The hardware passes all diagnostics. The Macintosh SE/30 has an HD80 SC, and the Macintosh IICx has an HD40 SC.

Can you explain why these things are happening?

DISCUSSION -----

There are two likely causes for these problems.

The first would be poor network connections or wiring that causes excessive packet loss and retries, resulting in poor performance. The second possibility is that the AppleShare File Server client stations are infected with the WDEF

virus.

Since you are reporting multiple occurrences of what seems to be the same problem, a cable or connector malfunction seems unlikely. We would suspect that the WDEF virus has spread at your sites.

While the WDEF virus does not appear to cause malicious damage (other than propagating), it does have bugs and side effects that are very annoying at best. It is spread via the Desktop file of Macintosh disks, and is activated when the Finder opens this file as part of its normal disk-mounting process. Once activated, WDEF copies itself to the Desktop files of other mounted volumes.

This virus effects server performance because it tries to infect the Desktop file of mounted server volumes as well as locally mounted disks. It first tests the target Desktop file to see if it's already infected, and if not, copies itself there. With network volumes, this activity requires many AFP (AppleTalk Filing Protocol) requests and is noticeably time-consuming on a LocalTalk- or PhoneNET-based network. This would be the effect you are noticing.

Fortunately, this virus is easy to detect and eliminate. One way is to scan your disks with a recent version of an anti-virus utility that has been updated to recognize the WDEF virus. Disinfectant 1.5, which is known to detect current strains of the WDEF virus as well as many other viruses, is one such utility. We recommend using it to scan all floppies and hard disks that may have been used recently.

Disinfectant 1.5 is also available under the AppleLink Developer Services icon by following this path:

- Developer Services
  - Macintosh Developer Technical Support
    - Tools
      - Virus Tools
        - Disinfectant 1.5

Disinfectant is capable of detecting and removing WDEF, but WDEF is also simple to remove by simply rebuilding the Desktop file of an infected disk. Hold down the Command and Option keys while the Macintosh is loading the Finder. Confirm the dialogs asking if you really want to rebuild the Desktop file on each mounted volume. The new Desktop file will be free of WDEF. Remember to restart the Macintosh after disinfecting volumes. This is necessary to remove any copies of WDEF that may be currently executing.

Another means of WDEF detection and removal is to use ResEdit. It allows you to view all the resources in a file, and can, therefore, be used as a primitive means of detection. If there are any WDEF resources present in a Desktop file, delete them. A normal Desktop file will not contain any WDEF resources.

To remove WDEF from server volumes, mount the volumes on a client Macintosh and use ResEdit to delete the server volume Desktop files. A Desktop file is not necessary on an AppleShare File Server volume, and by removing it you reduce

the risk of a future WDEF outbreak affecting server performance. Do not try to remove the files Desktop DB and Desktop DF. These are the files used by AppleShare instead of a Desktop file. They are not infected by WDEF, but are needed by AppleShare.

Other anti-virus software is available, both commercially and non-commercially, to detect viruses and to prevent future infections. SAM is a commercial package from Symantec Corp. that contains a detection and repair program from Symantec Corp. with similar functionality to Disinfectant. It also contains an INIT that alerts the user to, and prevents, infection attempts by known viruses.

There is also a public domain INIT, Eradicator!, that prevents infections of the WDEF virus, and removes any occurrences it detects.

We strongly recommend the installation of this or some similar type of program to help prevent infection.

For more information, search under: "Symantec" or "WDEF" or "Viruses".

## Apple Scanner: Unable To Be Recognized Problem

Revised: 3/4/90  
Security: Everyone

Apple Scanner: Unable To Be Recognized Problem

=====

This article last reviewed: 9 January 1990

TOPIC -----

I have had several problems with a Macintoshes SE/30 and my Apple Scanner.

When the Macintosh SE/30 is connected to the Apple Scanner, it doesn't recognize the scanner. The scanner does, however, work with a Macintosh IIX using the same cables and terminator.

I was finally able to make the connection between the Macintosh SE/30 and the scanner by putting a new hard drive in the SE/30, but I still don't know what the problem is.

DISCUSSION -----

You have a problem with impedance matching.

This is a known problem with the Apple Scanner. The situation occurs when the impedance created by a combination of devices and terminators on the SCSI chain causes one device to be "lost" on the chain.

There is no official service procedure. A workaround is to change the impedance of the SCSI chain by adding one or more terminators, SCSI devices, or an additional SCSI extender cable. The device in question should reappear.

## EtherTalk 2.0 and 802.3 Framing

Revised: 6/29/90  
Security: Everyone

EtherTalk 2.0 and 802.3 Framing

=====

This article last reviewed: 9 January 1990

TOPIC -----

Using a Macintosh II with the Apple EtherTalk Card, I hooked up and ran concurrently:

- 1) VersaTerm-Pro and Exodus X windows using a TSSnet transport providing login and X server capability to a DEC VAX running VMS and DECwindows.
- 2) NCSA Telnet and Exodus X windows using a Macintosh TCP/IP transport providing login and X server capability to a DEC VAX running Ultrix with X11 clients.
- 3) AppleShare Workstation using an AppleTalk transport to a DEC VAX running AlisaShare file server.

These three protocol stacks ran with Apple EtherTalk Phase 1 drivers, which use Ethernet framing, and ran concurrently without interference.

Would the above scenario work with Apple's EtherTalk Phase 2 drivers, which use 802.3 framing?

DISCUSSION -----

The IEEE divides the OSI Data Link Layer into the Logical Link Control (LLC) layer and the Medium Access Control (MAC) layer. It also developed the SubNetwork Address Protocol (SNAP) standard to accommodate the large number of protocols.

With EtherTalk Phase 1, AppleTalk data was transmitted in the data field of an Ethernet packet. With EtherTalk Phase 2, AppleTalk data is encapsulated in a SNAP packet, which is encapsulated in an LLC packet and transmitted in a CSMA/CD 802.3 packet.

Though EtherTalk Phase 2 uses the SNAP interface, higher-level protocols can go directly to the LLC layer without using SNAP. SNAP allows for connectionless communication services only.

1 and 2)

These higher protocols go directly to the LLC layer and use the Ethernet driver for the EtherTalk Card instead of using our higher-level EtherTalk 2.0 software. They should work fine.

3) This should work fine when Phase 2 support for AppleTalk for VMS is released.

## Macintosh OS C Compiler and Draft ANSI Standard

Revised: 3/4/90  
Security: Everyone

Macintosh OS C Compiler and Draft ANSI Standard

=====

This article last reviewed: 9 January 1990

TOPIC -----

Do the Macintosh OS and A/UX C compilers meet the ANSI standard X3J11 draft X3.259? I need to include that information in a proposal.

DISCUSSION -----

The C compiler that comes with A/UX is NOT compatible with the draft ANSI standard for C. (The A/UX C compiler is the standard System 5.2.2 release compiler.)

Under the Macintosh OS, the MPW 3.0 C compiler was written to move towards the ANSI draft standard, but since the standard is at a draft stage, engineering has a moving target.

However, if you read Appendix D of the MPW 3.0 C reference manual (APDA #M0022LL/A) you will see that the majority of the changes to the C compiler were implemented for ANSI compatibility.

Both Appendix D and the Release Notes have sections pertinent to ANSI compatibility. Read them for further information.

## Monitors Control Panel: Special Gamma Function Explained 1/93

Revised: 1/21/93  
Security: Everyone

Monitors Control Panel: "Special Gamma" Function Explained 1/93

=====

Article Created: 9 January 1990

### Article Change History

-----

09/14/92 - REVISED

- To provide additional information.

01/21/93 - REVISED

- To add more detailed instructions for changing Gamma settings.

### TOPIC -----

Can you provide any information on the Special Gamma function in the Monitors control panel?

### DISCUSSION -----

#### How to Change the Gamma Setting

-----

Special Gamma allows different gamma tables to be selected. You access it through the Monitors control panel:

- By holding down the Option key while clicking the "Options..." button  
or
- By holding down the Option key while double clicking the happy Mac face that appears in the monitor window.

Now you get a dialog box where you can change the setting:

1) Check the "Use Special Gamma" checkbox.

2) Highlight the "Mac HiRes Std Gamma" or "Uncorrected Gamma" in the scroll box.

3) Restart the computer.

#### An Example of Special Gamma Table Use

-----

A company has a video card that supports the two different displays that they sell. Unfortunately, these two displays show colors differently on the screen. Being able to select the gamma table allows the company to make both displays generate comparable colors to the viewer's eye.

The following information is on page 9-16 of "Designing Cards and Drivers for the Macintosh II and Macintosh SE" (Addison Wesley, ISBN #0-201-19256-X):

"The gamma table compensates for nonlinearities in a display's color response by providing either a function or a look-up value that associates each displayed color with an absolute RGB value. It is used to modify a video card's color look-up table. The gamma table is described in the chapter 'Graphic Devices' of Inside Macintosh Volume V (Addison Wesley, ISBN #0-2-1-17719-6)."

Displays that don't use gamma-table correction tend to look over-saturated and dark. Although determining the correct values for a gamma table can be difficult without special tools, the table's contribution to image quality can be striking.

## Macintosh IICI: Two-Page Monitors Need NuBus Video Card

Revised: 7/9/92  
Security: Everyone

Macintosh IICI: Two-Page Monitors Need NuBus Video Card

=====

Article Created: 9 January 1990  
Article Last Reviewed: 8 July 1992  
Article Last Updated: 8 July 1992

### TOPIC -----

Does the Macintosh IICI support the Apple Portrait Display and Apple 2-page Monochrome Monitor? I've heard that it doesn't.

### DISCUSSION -----

The Macintosh IICI has the equivalent of a video card built into the main logic board. Other video cards can be added to any one of the three NuBus slots.

The built-in video circuitry supports:

- Apple Macintosh 12" RGB Display (@ 2, 4, 16, and 256 colors or levels of gray)
- Apple High-Resolution Monochrome Monitor (@ 2, 4, 16, and 266 levels of gray)
- AppleColor High-Resolution RGB Monitor (@ 2, 4, 16 and 256 colors or levels of gray)
- Apple Macintosh Portrait Display (@ 2, 4, and 16 levels of gray)

Therefore, the Two-Page Monochrome Monitor does not work if simply connected to the built-in video circuitry, but WILL if used with its respective NuBus video card.

All the other monitors mentioned will also work if connected to the Macintosh IICI through compatible NuBus cards.

Icons: Bibliography on Design

=====

Article Created: 4 March 1990  
Article Reviewed/Updated: 26 July 1993

TOPIC -----

Does Apple have international icons? I want to create a database and use it in different countries by displaying icons in a universal way.

DISCUSSION -----

We strongly recommend that you obtain one or more of the numerous symbols dictionaries or dictionaries of icons, often available from graphic-arts, graphic-design, and technically oriented bookstores. Some of these reference dictionaries are listed at the end of this document. These dictionaries are helpful when creating and implementing icons.

We request and obtain design patterns for many of the icons created at Apple, after which Apple Legal is generally open to them being used by developers -- but for their designed purpose only, such as being used in Macintosh software that runs on the Macintosh, not for porting to other platforms.

Though Apple has no list of icons that are distributed, the icons Apple developed can be found in many locations, including user and technical manuals, the Icon Stack in HyperCard, advertisements, and so on. They are also visible in the system software.

Among the many programs that allow you to create and edit icons are ResEdit from APDA and Icon-It! from Tactic Software.

Also, Icon Factory from HyperPress Publishing Corporation contains more than 2,000 icons that can be used to customize HyperCard stacks.

## Macintosh Portable: Connecting External SCSI Devices

Revised: 7/28/92  
Security: Everyone

Macintosh Portable: Connecting External SCSI Devices

=====

Article Created: 9 January 1990  
Article Last Reviewed: 28 July 1992  
Article Last Updated: 28 July 1992

TOPIC -----

I've had numerous problems connecting external SCSI devices to Macintosh Portables. I've tried three Portables with several external SCSI drives and printers.

When I tried to start up the Macintosh Portable with an external SCSI drive attached, I received the question mark icon. After I disconnected the SCSI system cable from the Portable, the internal hard immediately kicked in and started up the machine.

Once the machine started up, I connected the drive and tried to mount it with a SCSI CDEV utility. I was able to do so once, but in every other instance, the utility was unable to identify the SCSI address of the external drive or mount it. In fact, SCSI address 0 disappeared when the external drive was connected, and nothing requiring internal hard disk access could be done until the external drive was disconnected. This corresponded with the symptoms while starting up; apparently the entire SCSI bus was disrupted. However, SCSI address 7 remained intact.

Can you explain what's going on? Any ideas?

DISCUSSION -----

We have, on different occasions, connected numerous types of external hard drives to the Macintosh Portable. In all cases, the drives and the Macintosh Portable functioned properly.

Make sure you're using:

- Proper termination and good terminators

- Good cables
- The SCSI number on the peripheral is something other than 7 (reserved for the CPU) and 0 (if you have an internal hard disk).
- The external drive is not damaged. (If it is damaged, it may not be providing proper termination power.)
- The external drive is connected and powered on before you start up the Macintosh Portable.

We suspect that your problem may be caused by the last variable.

The Macintosh Portable does not provide termination power, so any external SCSI devices connected to the Macintosh Portable must be turned on and ready. Termination power is required for the terminator to terminate the SCSI bus. Until external SCSI devices are powered on and ready, the Macintosh Portable will not start up. The external SCSI devices must remain on while using the Macintosh Portable, or the system will hang. If you erroneously turn off an external device and the Macintosh Portable hangs, you can sometimes resume by turning the SCSI device back on.

The proper and safest way to add SCSI devices to the Macintosh Portable is to first turn off the Macintosh Portable using the Shut Down function. Also make sure the external SCSI devices are turned off. Your external SCSI devices can then be plugged in without damaging the Macintosh Portable.

## Using Macintoshes on Token Ring Network

Revised: 3/4/90  
Security: Everyone

Using Macintoshes on Token Ring Network

=====

This article last reviewed: 9 January 1990

TOPIC -----

I want to implement the following:

- 1) Macintosh IIcx connection direct on 16MB Token Ring.
- 2) Macintosh IIcx connection from a 4MB Token Ring to a 16MB Token Ring via some router or gateway and then onto an Ethernet backbone (Cabletron twisted-pair).

I currently have 180 +/- 15 systems on the network during peak periods. IBM will be putting in Model 80s supposedly with Office Vision in March. If they cannot make the deadline, they will use OS/2 and Windows-PM. Connectivity between the IBM and Apple systems would be very helpful.

There are some programs that may need to work in both residential areas (one session in the IBM camp, the next in the Apple camp). I cannot rewire the other buildings once the IBM wire is in place, so I need to connect to the 16MB Token Ring somehow.

DISCUSSION -----

The TokenTalk NB Card does not support 16MB Token Rings, and we are not aware of a product for the Macintosh that will connect directly to a 16MB Token Ring. Therefore, we are not able to suggest a solution for option #1.

For option #2, there is a possibility. IBM has software for a PC that provides source-level routing between two Token Ring networks (including routing between a 4MB and a 16MB network). Since TokenTalk supports source-level routing, the TokenTalk packets would be routed by this bridge. The name of this IBM software product is "Token Ring Bridge Program".

One possible configuration for the network you described is:

Put the Macintoshes on a 4MB ring. This 4MB ring would be connected to the 16MB ring via a PC with two Token Ring cards (one 4MB and one 16MB).

Routing to the Ethernet will be somewhat trickier. You could have another PC running the bridge program as described above. Connected to the 4MB side of this machine would be a Macintosh with a TokenTalk NB Card and an EtherTalk Card running the Apple Internet Router.

This configuration will route only AppleTalk packets onto the Ethernet. Some other device would have to be responsible for routing other protocols onto the Ethernet.

## Macintosh Portable: Battery Rating

Revised: 7/30/92  
Security: Everyone

Macintosh Portable: Battery Rating

=====

Article Created: 9 January 1990  
Article Last Reviewed: 30 July 1992  
Article Last Updated:

TOPIC -----

An Australian customs tariff for Macintosh Portable batteries states that the following requirement must be met:

"Accumulators, lead acid, including gel and lead calcium types, permanently sealed, rechargeable, capacity NOT exceeding 11 amp-hours at the 20-hour rate."

What is meant by the 20-hour rate, and do our Portable batteries fall within this rate?

DISCUSSION -----

The 20-hour rate is an indicator of battery capacity, a measure of how much current is required to drain the battery over a 20-hour period. Macintosh Portable batteries carry a rating of 5.4 amp-hours at 20 hours, so they fall within this guideline.

## Apple Portrait Display: Video Card Pinouts

Revised: 10/22/90  
Security: Everyone

Apple Portrait Display: Video Card Pinouts

=====

This article last reviewed: 9 January 1990

TOPIC -----

I need the pinouts for the new Portrait Display Video Card that uses the DB-15 connector. I also need the pinouts of the cable that connects the new DB-15 card to the WD-13 on the Portrait Display.

DISCUSSION -----

The pinouts for the new version of the Portrait Display Video Card are identical to those of the Macintosh IIci built-in video connector.

| Pin   | Signal      |                      |
|-------|-------------|----------------------|
| ---   | -----       |                      |
| 01    | RED.GND     | Red Video Ground     |
| 02    | RED.VID     | Red Video            |
| 03    | CSYNC       | Composite Sync.      |
| 04    | MON.ID1     | Monitor ID, Bit 1    |
| 05    | GRN.VID     | Green Video          |
| 06    | GRN.GND     | Green Video Ground   |
| 07    | MON.ID2     | Monitor ID, Bit 2    |
| 08    | nc          | (No Connection)      |
| 09    | BLU.VID     | Blue Video           |
| 10    | MON.ID3     | Monitor ID, Bit 3    |
| 11    | C&VSYNC.GND | CSYNC & VSYNC Ground |
| 12    | VSYNC       | Vertical Sync.       |
| 13    | BLU.GND     | Blue Ground          |
| 14    | HSYNC.GND   | HSYNC Ground         |
| 15    | HSYNC       | Horizontal Sync.     |
| Shell | CHASSIS.GND | Chassis Ground       |

The finished-goods part number for this cable is #590-0615.

The pin requirements for a cable between a new version of the Portrait Display

Video Card (or a Macintosh IIci) and a Portrait Display are as follows:

| DB-15<br>(On Card) | Signal      | D Series-Size 3<br>(On Display) |
|--------------------|-------------|---------------------------------|
| -----              | -----       | -----                           |
| 1                  | RED.GND     | A3 (Outer)                      |
| 2                  | RED.VID     | A3 (Center)                     |
| 3                  | CSYNC       | 5                               |
| 4                  | MON.ID1     | 9                               |
| 5                  | GRN.VID     | A2 (Center)                     |
| 6                  | GRN.GND     | A2 (Outer)                      |
| 7                  | MON.ID2     | 8                               |
| 8                  | nc          |                                 |
| 9                  | BLU.VID     | A1 (Center)                     |
| 10                 | MON.ID3     | 3                               |
| 11                 | C&VSYNC.GND | 4,7,10                          |
| 12                 | VSYNC       | 2                               |
| 13                 | BLU.GND     | A1 (Outer)                      |
| 14                 | HSYNC.GND   | 1                               |
| 15                 | HSYNC       | 6                               |
| Shell              | CHASSIS.GND | Shell                           |

Following are the signal assignments for the Portrait Display D-series size 3 connector, shown from the back of the monitor.

| Pin   | Signal Name             |
|-------|-------------------------|
| ---   | -----                   |
| A1    | Monochrome video        |
| A2    | 75-ohm                  |
| A3    | 75-ohm                  |
| 1     | Hsync return            |
| 2     | Vsync                   |
| 3     | Sense #3                |
| 4     | Sense ground            |

## AppleShare PC And Lotus Printing Problem: Use Freelance Plus

Revised: 3/4/90  
Security: Everyone

AppleShare PC And Lotus Printing Problem: Use Freelance Plus

=====

This article last reviewed: 9 January 1990

TOPIC -----

Configuration  
-----

- Lotus version 2.0.1 (with the Lotus Value Pack, which provides PostScript printer support. Before this, PostScript was not supported.)
- DOS versions 4.0 and 3.2 and Compaq 3.3. The problem is the same with all versions.
- AppleShare PC 2.0 with LocalTalk
- LaserWriter Driver 6.0 on LaserWriter IINTX
- Impress, which allows Lotus users to combine text and graphics on the same page. It has its own printer drivers.

Problem  
-----

When I am sending jobs to the printer, there is some communication going on between the PC and the LaserWriter. The PC is flashing the wait message, and the green light on the LaserWriter is flashing, but eventually the PC displays a "system error" and needs to be restarted.

DISCUSSION -----

We tested the problem you described and also got an error when trying to print to the LaserWriter IINTX. Using a LocalTalk packet Peek program, we could not find any PostScript code in the packets sent to the printer. We double-checked our installation of the PostScript drivers, and still got no PostScript code output from Lotus.

While verifying the installation, we found something that describes the above behavior: the Lotus Value Pack uses CONFIG.SYS to support PostScript. To use the PostScript drivers, you must install the DOS device driver, LOTUSPS.SYS, in the CONFIG.SYS file. To do this, Lotus has to intercept interrupt 17, which is used by MS-DOS for printing.

Since AppleShare PC is loaded after CONFIG.SYS, and it also intercept interrupt 17 to direct printing traffic over the AppleTalk network, AppleShare PC claims ownership of interrupt 17. Therefore, when you print from Lotus, AppleShare PC gets the data and sends it over the network to the printer because it assumes the data is in PostScript, and the Lotus device driver in CONFIG.SYS does not have a chance to convert it to PostScript.

The new version of Freelance Plus from Lotus -- which is smaller memory-wise and runs on all of the machines -- comes with a PostScript driver that not only works across the AppleTalk network, but can open and print the Lotus Printgraph files.

As you know, you can also use a Lotus "add-on" package, such as Allways or Impress, as a workaround.

## AppleShare PC & InterLAN Ethernet Card Compatibility

Revised: 8/28/90  
Security: Everyone

AppleShare PC & InterLAN Ethernet Card Compatibility

=====

This article last reviewed: 9 January 1990

TOPIC -----

I work with a company that thousands of PCs. We are now buying into Macintosh technology in a big way but are concerned with PC use.

We are very big UNIX users and rely totally on NFS to supply us with our file server needs. On the PC side, we are using PC NFS, which allows them to use an Ethernet card from InterLAN.

We would like to use AppleShare PC, but only if we don't have to replace all our Ethernet cards. Has AppleShare PC has been tested with the InterLAN card?

DISCUSSION -----

AppleShare PC 2.0 has not been tested with InterLAN's Ethernet card. Since Apple and Novell published the Open Datalink Interface (ODI), the third-party vendors are responsible for providing drivers to ensure compatibility.

ODI allows a separation between the network protocol stacks and the device driver. These drivers are specific to a particular network media, such as LocalTalk, Ethernet, or Token Ring. AppleShare PC 2.0 includes drivers for:

- 3COM's EtherLink II and EtherLink/MC (MicroChannel)
- Three IBM 802.2 Token Ring cards
- Apple's LocalTalk PC Card
- DayStar Digital's MCA LocalTalk Card (MicroChannel)

The best way to find out if this will work is to contact InterLAN to see if they support the Novell/Apple ODI specification -- or, if possible, to run a test with an InterLAN Ethernet card.

## Macintosh Finder: fPRT Resource Not a Virus

Revised: 7/19/91  
Security: Everyone

Macintosh Finder: fPRT Resource Not a Virus

=====

Article Created: 18 January 1990  
Article Last Reviewed: 2 February 1991  
Article Last Updated:

### TOPIC -----

Is there an fPRT virus? Something appears to have added 144 bytes to the System 6.0.3 Finder and a new fPRT resource.

Is there anything strange about an fPRT resource being added to the Finder?

### DISCUSSION -----

The existence of the fPRT resource in the Finder is not an indication of a virus. Although there is no fPRT resource in the Finder as it is shipped on System Software disks, it is a resource belonging to the Finder. When you choose Page Setup from the Finder's File menu, the Finder stores the settings you have chosen in an fPRT resource for future reference.

## WDEF Virus: Information

Revised: 3/4/90  
Security: Everyone

"WDEF" Virus: Information

=====

This article last reviewed: 18 January 1990

TOPIC -----

This article contains information on spotting and neutralizing a new virus (sometimes called the "WDEF virus")

DISCUSSION -----

There is a Macintosh virus (sometimes called the "WDEF virus") that uses a different method to transfer itself between machines. Because this virus attaches itself to the Desktop file of a disk, it infects a hard disk when the infected floppy disk is inserted into the Macintosh.

If you want to check a disk for infection, follow these steps:

- 1) Start your machine in Finder, NOT MultiFinder.
- 2) Run ResEdit.
- 3) Insert the suspect floppy disk.
- 4) Open the Desktop file.
- 5) If it contains a WDEF resource with ID=0, it is infected.

If you insert an infected floppy disk when running MultiFinder, the Desktop file is automatically opened, and your system will be infected.

There is a way to keep this virus from infecting your system:

- 1) Your current application must be the Finder. If you are running MultiFinder, you should have the Finder's menus in the menu bar.
- 2) Hold down both the Command and Option keys.

- 3) With these keys held down, insert the unlocked floppy disk.
- 4) You will be asked if you want to rebuild the Desktop file.
- 5) Choose "Yes". If you choose "Cancel" at this point, and the floppy is infected, you will infect your system.

Rebuilding the Desktop removes the virus.

As of February 1990, Apple is aware of several virus tools that can automatically detect this virus:

- SAM v1.5
- AntiToxin v1.3
- Virex v2.3
- Disinfectant v1.6
- Eridicator (Public Domain)
- Kill WDEF (Public Domain)

For more information, search on the above product names in the Tech Info Library.

## Macintosh Portable: Battery DA Doesn't Exactly Measure Charge

Revised: 7/30/92  
Security: Everyone

Macintosh Portable: Battery DA Doesn't Exactly Measure Charge

=====

Article Created: 18 January 1990  
Article Last Reviewed: 30 July 1992  
Article Last Updated: 8 July 1991

TOPIC -----

I am evaluating 10 Macintosh Portables.

Eight were removed from their shipping materials and charged for 4 to 5 hours. They were then left untouched for 4 hours, and as soon as they were activated, the battery DA indicated that there was only a 3/4 charge.

After examining the documentation, it was apparent that the battery should be charged for at least 10 hours. Macintosh Portables number 9 and 10 were then charged (for the first time) for 12 and 24 hours, respectively.

From this point on, all systems were treated and behaved in essentially the same ways. When one system was tested, the "battery-low" warning appeared after only 3 hours of non-continuous use. On some occasions, after charging, the battery DA would say 3/4 full, then, although the machine had not been used, it would indicate almost completely full 2 hours later. On other occasions, one could actually watch the battery power level go down.

Is this kind of activity to be expected from the Portable Battery?

DISCUSSION -----

The Battery DA is not an exact representation of battery state.

It indicates battery-low conditions by comparing the current battery state to the power curve of a "typical" Macintosh Portable battery. Since the actual curve for all batteries is not the same (some start higher and decay slower), the output of the DA cannot be considered exact.

A perception problem may also exist in regards to the portable battery DA. When the hard drive wakes up or the back lighting is turned on and off the battery DA fluctuates a significant amount. Many customers interpret this a 1 to 1 voltage drain on the battery and think their battery has suddenly lost most of it's voltage. Because of the increased load of the back-lighting the battery DA will fluctuate even more than it did on the original non-backlit portable. It is important that the customer understand that the batter DA is only a "rough" estimate of the battery voltage level and will vary significantly according the current load on the system.

(NOTE: Even after the first warning is received, the user should have about an hour before hardware shutdown occurs.)

There are many possible explanations for the situation you report: namely, the DA indicating a higher charge after the Macintosh sits inactive for a while.

First, a warm battery indicates a higher charge than a cold one. If the first reading was taken immediately after bringing the Macintosh Portable indoors, the DA would show a higher charge after the system reached room temperature. The same could hold true with the system operating.

The estimated time before the battery needs recharging depends on how the system is being used. For example, the charge life of a hard disk-equipped Macintosh Portable would be closer to 6 hours, while the same system using a RAM disk would last closer to 12 hours. The how-long-until-sleep setting in the Macintosh Portable CDEV also changes battery life. Also, floppy disk-intensive applications require more power than those that use the more efficient hard disk.

As far as the low-power warning appearing after only 3 hours, it's unclear whether that system was one of the original eight that were undercharged to begin with. It's important to remember that the Macintosh Portable battery is lead-acid and not ni-cad. Ni-cad batteries benefit if they are charged completely and then fully drained each time. Lead-acid batteries are just the opposite; the more charged you keep the battery, the longer it holds a charge.

## Macintosh IIci: How To Disable Built-In Video

Revised: 7/9/92  
Security: Everyone

Macintosh IIci: How To Disable Built-In Video

=====

Article Created: 18 January 1990  
Article Last Reviewed: 8 July 1992  
Article Last Updated:

TOPIC -----

Is it possible to disable the Macintosh IIci system's built-in video?

If so, does this mean that I can improve the Macintosh IIci computer's performance by adding a video card to the NuBus slot?

DISCUSSION -----

Yes, it is possible to disable the built-in video of the Macintosh IIci:

- 1) Leave the RAM SIMM bank A empty.
- 2) Don't connect a monitor to the built-in video connector.

The built-in video circuitry disables itself if there is no RAM in bank A or if it fails to recognize a compatible monitor attached to the connector. The Macintosh IIci and the new version of the Macintosh II Video Card identify monitors by checking the states of three ID lines in the cable between the computer and the monitor. If no monitor is connected, it disables itself.

Using a NuBus video card can increase or decrease "performance", depending on what work is being done on the Macintosh IIci. The effect of built-in video's cycle-stealing on RAM bank A can reduce the speed of anything that accesses data in that bank by 6 to 51%, depending on the monitor and bit depth being used. On the other hand, moving large amounts of video data to the built-in video is faster than moving it over NuBus to a video card because there is no 10MHz NuBus limitation with built-in video.

What all this means is that a low-computation, high-graphic program tends to run faster on the built-in video, while a high-computation, low-graphic program tends to run faster with a NuBus video card. Optimal system configuration depends on what the Macintosh IIfx is used for.

DayStar Digital's FastCache Card can help offset the cycle-stealing performance penalty.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

## Multiple Sessions Possible On VAX Systems

Revised: 3/4/90  
Security: Everyone

Multiple Sessions Possible On VAX Systems

=====

This article last reviewed: 18 January 1990

TOPIC -----

I'm using the White Pine Mac241 product as a terminal emulator for my two VAX systems, and I want to do multiple sessions on the VAX systems -- a session on each at the same time over LocalTalk. Does the LAT protocol needs to be supported to do this?

I think multiple VAX sessions are possible, but I do not know if the White Pines product supports it. Can you help?

DISCUSSION -----

Digital's Local Area Transport (LAT) architecture is a set of protocols used by terminal servers to communicate with host computer systems over a high-bandwidth, high-reliability communications channel.

Multiple VAX sessions are currently supported by White Pine Mac240 and Mac241 using Digital's CTERM Network Protocols implemented in Alisa TSSnet. Any terminal emulators using the WPIO interface (as defined by White Pine Software) are supported. Contact Alisa for more particular information on the interface.

For more information, search under: "Alisa Systems" and "White Pine"

## Macintosh IICx: Purpose of Jumper W3

Revised: 7/14/92  
Security: Everyone

Macintosh IICx: Purpose of Jumper W3

=====

Article Created: 18 January 1990  
Article Last Reviewed: 10 July 1992  
Article Last Updated:

TOPIC -----

What is the purpose of jumper W3 on a Macintosh IICx logic board?

DISCUSSION -----

The W3 jumpers are put in place after the testing phase of Macintosh IICx production is completed. When removed, the test equipment can arbitrate directly with the MC68030 microprocessor. They should never be removed unless the logic board is being serviced by factory technicians.

Though the jumpers shouldn't be removed, the logic board will function properly without them -- as long as there is no bus master card, such as an accelerator, in any of the NuBus slots.

## AppleShare PC: Selecting a Printer From Microsoft Windows

Revised: 3/4/90  
Security: Everyone

AppleShare PC: Selecting a Printer From Microsoft Windows

=====

This article last reviewed: 18 January 1990

TOPIC -----

When I try to print to a LaserWriter from PageMaker on a DOS machine (using AppleShare PC 1.1), nothing happens.

Other than during installation of Microsoft Windows and in PageMaker (where you can choose from the printers that are defined in WIN.INI) is there any other place to define what kind of printer you are going to use?

DISCUSSION -----

When you first set up Microsoft Windows, you select the printer you'll use with your system. To change this selection, use the Add New Printer and Delete Printer commands from the Installation Menu in the Control Panel (run CONTROL.EXE from the MS-DOS Executive window).

Also, from the Setup Menu in the Control Panel, you can use the Printer command to specify a system default printer and set its output modes.

The system default printer is the printer that applications designed for Microsoft Windows will use. Printer output modes are printer-specific settings, such as Portrait versus Landscape, or color for plotters.

## TokenTalk: Source-Level Routing

Revised: 3/4/90  
Security: Everyone

TokenTalk: Source-Level Routing

=====

This article last reviewed: 18 January 1990

TOPIC -----

Does you know what bridges/routers were used to test the IBM Source Routing capability of the Apple TokenTalk NB Card? Were there any incompatibilities with the AppleTalk Internet Router running in AppleTalk Phase 2 mode or with the Upgrade Utility? Is there a version of Peek that supports the AppleTalk Phase 2 and/or Token Ring LAP?

DISCUSSION -----

The source-level routing that was used to test the TokenTalk NB Card and TokenTalk software was IBM's Token Ring Bridge Program running on a PC. However, any product that provides source-level routing should work with TokenTalk. There should be no compatibility problem with the Internet Router and the Upgrade Utility.

LocalTalk Peek can be used with both AppleTalk Phase 1 and Phase 2 networks. We are not aware of any TokenTalk Peek.

## AppleTalk Phase 2: Network Nodes Store Recent Network Info

Revised: 3/4/90  
Security: Everyone

AppleTalk Phase 2: Network Nodes Store "Recent" Network Info

=====

This article last reviewed: 18 January 1990

TOPIC -----

On an AppleTalk Phase 2 network that has multiple levels of routers, does the workstation retain information about the local router or about all routers that exist on the network?

DISCUSSION -----

EtherTalk 2.0 and TokenTalk 2.0 nodes store information about "recently heard from" networks and routers. The node does not store information about all routers on the Internet.

The first two paragraphs below are from the AppleTalk Phase 2 specification:

"The following information applies to AppleTalk Phase 2 nodes only. It is desirable for nonrouting nodes to send each packet to the router yielding the shortest route to the packet's destination network--the "best" router. Although the current specification does not require this, an optional strategy follows for implementing a "best routing" DDP algorithm in nonrouting nodes.

"When a packet arrives from an off-network node, DDP reads the data-link-level source. This is the address of the last router on the route from the originating network. This router should generally be the optimal "next router" -- in terms of hops -- in the route back to that network. DDP maintains a cache of "best routers" for "recently heard from" networks, and sends packets to those routers for forwarding to those networks. If there is no cache entry for a network, DDP sends the packet to any router, expecting that a response packet will provide the information necessary to make an entry into the cache."

The algorithm in the preceding paragraph is used by EtherTalk 2.0 and TokenTalk 2.0 nodes. The phrase "recently heard from" networks means, in Apple's implementation, networks that the node has heard from in the last 40 seconds or so. After that, the cache is cleared of the network entry.

AppleTalk: Where to Find Encryption Algorithm Information

=====

This article last reviewed: 3 April 1990

TOPIC -----

I am putting together a file server on a mainframe and need information on the password encryption algorithm Apple uses.

Does Apple publish that information?

DISCUSSION -----

Inside AppleTalk (Addison Wesley, ISBN #0-201-19257-8), pages 13-28 to 13-30, discusses user authentication methods. Pages 13-29 and 13-30 discuss the AFP random exchange authentication method, which uses the NBS DES (National Institute of Standards and Technology Data Encryption Standard) algorithm.

For more specific answers about this algorithm -- or to get the algorithm itself -- contact the National Institute of Standards and Technology.

We also found a DES encryption program written in C starting on page 262 of a book called "UNIX System Security". The book, written by Patrick H. Wood and Stephen G. Kochan, is published by Hayden Books (ISBN #0-8104-6267-2).

Mathematica: Using Macintosh as a NeXT Front End

=====

This article last reviewed: 18 January 1990

TOPIC -----

I want to use my Macintosh as a front end for Mathematica running on my NeXT computer. Is this possible?

DISCUSSION -----

According to Wolfram Research Technical Support, the Macintosh CAN be used as a front end for Mathematica running on the NeXT computer.

To do this, you need Mathematica for the Macintosh and the NeXT. Wolfram has a document called "Macintosh TCP/IP Installation Guide" -- free to registered owners of Mathematica -- that describes how to use MacTCP and Mathematica to connect to the NeXT computer and how to use the Mathematica kernel on the NeXT computer. To get this document, contact Wolfram Research Technical Support.

## System 6.0.4: ColorSnap and Macromind Director Compatibilty

Revised: 3/4/90  
Security: Everyone

System 6.0.4: ColorSnap and Macromind Director Compatibilty

=====

This article last reviewed: 29 January 1990

TOPIC -----

Is ColorSnap 32 by Computer Friends and Macromind Director by Macromind compatible with System Software 6.0.4?

DISCUSSION -----

Computer Friends Tech Support states that ColorSnap 32 works fine with System Software 6.0.4. Since their new systems haven't arrived, they haven't tested ColorSnap 32 with a Macintosh Portable or Macintosh IIfx.

MacroMind released MacroMind Director 1.0.1 the same day that the Macintosh Portable and Macintosh IIfx were announced. Though MacroMind Director 1.0.1 is compatible with these new systems and System Software 6.0.4, earlier versions of Director are not. For a free upgrade, contact Macromind.

For more addresses and phone numbers, search the Technical Info library under "Computer Friends" and "Macromind."

## Macintosh: How To Determine Pantone Color Wheel Equivalents

Revised: 3/4/90  
Security: Everyone

Macintosh: How To Determine Pantone Color Wheel Equivalents

=====

This article last reviewed: 23 January 1990

TOPIC -----

I need documentation on the color wheel. I would prefer a chart that provides color information that can be typed into a color-wheel dialogue box. For example:

Forest green is composed of:

Hue: #####  
Saturation:#####  
Brightness:#####  
Red:#####  
Green:#####  
Blue:#####

DISCUSSION -----

Apple doesn't have a chart correlating the color wheel entries with the Pantone color chart. Although there are third-party products that display (dithered) Pantone colors on the screen and create color separations for output to a PostScript typesetter, these programs usually don't offer a formula or prescribed way to input values to obtain a specific output.

Many of those products can be located by searching on "Pantone" in the buyer's guides (Menu and Redgate libraries) on AppleLink. The only way we know of to achieve "Pantone" input values is to conduct a color analysis, entering then logging values on a match with a desired output. You can find to the color wheel and related managers, procedures, and so on in the "Inside Macintosh Cross-Reference."

## Macintosh: Connecting to an IBM 3090 with a ITT Courier 9440

Revised: 3/4/90  
Security: Everyone

Macintosh: Connecting to an IBM 3090 with a ITT Courier 9440

=====

This article last reviewed: 23 January 1990

TOPIC -----

At work, they are replacing an ITT Courier 9212 terminal (connected with coax cable) with the Macintosh using a channel-attached ITT Courier 9440 "Local Controller" (some kind of cluster controller).

Do you have any idea what this ITT Courier 9440 is? Is it a direct replacement for a 3274 cluster controller? Does the ITT Courier 9212 emulate a 3270 terminal? Is this going to work with the Macintosh?

DISCUSSION -----

The ITT Courier 9440 is a 3274-A/41-A channel-attached controller. The ITT Courier 9212 does emulate a 3270 terminal. Therefore, you can substitute the Courier 9212 with a Macintosh running MacTerminal and an IrmaLine from DCA. For more details, search the Technical Info library under "DCA".

## Netware for Macintosh 1.1: Enhancements and Fixes

Revised: 3/4/90  
Security: Everyone

Netware for Macintosh 1.1: Enhancements and Fixes

=====

This article last reviewed: 23 January 1990

TOPIC -----

Here's information on enhancements and fixes for Netware version 1.1 for Macintosh. Note that Netware 2.1.5 revision C must be used.

DISCUSSION -----

Enhancements:

- The NL/2 board is now supported.
- The Netware Control Center (an application that lets you view and modify network information) has been enhanced.
- System administrative functions (adding and deleting users and groups ONLY) can be done from the Macintosh workstation.

Problems that Have Been Fixed:

- IBM Token Ring Adapter (16K buffer)/shared memory address problem
- Losing connections with the file server
- Print queue losing connections with the file server
- File server not displayed in Chooser window
- File server could not read settings file for AQS and APS print VAPs

To obtain these updates, send Novell the following:

- Your name, address, and phone number

- If you are ordering the Netware update, designate disk size: either 3.5 or 5.25)
- Proof of Purchase (copy of invoice)
- A list of desired items.

You can Fax or mail your order to Novell. the information to 801-377-6743 or mail the data to:

## Macintosh: Converter Is Necessary for V.35 Support

Revised: 6/18/92  
Security: Everyone

Macintosh: Converter Is Necessary for V.35 Support

=====

Article Created: 23 January 1990  
Article Last Reviewed: 18 June 1992  
Article Last Updated:

TOPIC -----

How should a Macintosh DIN-8 port be connected for V.35 cabling specifications? The clocking for the signal will be from an external device like a DSU.

DISCUSSION -----

Although the built-in serial ports cannot directly support V.35 (due to the multiple timing/clocking elements the port must support), third-party converters are available to convert RS-232 or RS-422 to and from V.35. Such converters are available from Black Box and others. Additionally, depending on the application or functionality desired, the Serial NuBus card also supports V.35.

## Xerox 6085 Data: Converting it to Macintosh Format

Revised: 3/4/90  
Security: Everyone

Xerox 6085 Data: Converting it to Macintosh Format

=====

This article last reviewed: 29 January 1990

TOPIC -----

I have decided to change my office's Xerox desktop publishing systems (Documentor 6085) to Macintoshes. What do you recommend in the way of a document-conversion utility to convert the Documentor 6085 text and graphic documents to Macintosh formats.

DISCUSSION -----

We don't know of any commercial conversion utilities that convert Xerox 6085 graphic files into a format recognized by the Macintosh. However, there are numerous ways to convert text.

You can find some Xerox 6085-to-Macintosh file conversion tips are in the Tech Info Library document "Macintosh-to-Xerox 6085 Connectivity" and in the Xerox Technical Bulletin "Xerox 6085 Interface to Macintosh". Additionally, conversion services like Pivar, Inc. will convert Xerox 6085 files to Macintosh.

The Tech Info Library article references Interpreter, Inc. For address details, search the Tech Info Library on "Pivar" and "Interpreter, Inc".

## Macintosh: Alternatives to Using a Mouse

Revised: 3/4/90  
Security: Everyone

Macintosh: Alternatives to Using a Mouse

=====

This article last reviewed: 29 January 1990

TOPIC -----

I have little feeling in my hands, so I cannot sense where the button is. This means I cannot use the new-style ADB mouse, because of the angle of the mouse and because the mouse button is recessed.

On the old-style mouse, the angle of the mouse was such that my arms could bend properly, and I could tell when my hand was on the raised mouse button. What can I do to use the newer Macintoshes?

DISCUSSION -----

Because of mechanical and electrical design differences between the old-style mouse and the ADB mouse, you cannot modify an old-style mouse for use with ADB. However, there are a number of different vendors producing alternative input devices for use with the ADB interface. Listed below is information about several of these third-party products. You may also want to check the trade journals for other types of ADB input devices.

A+ Mouse and A+ Mouse ADB from Mouse Systems Corp.

-----

A+ Mouse is an entirely electronic and consists of no moving parts. It uses its own mirror-like pad to reflect a tiny beam of light to track movement. It has exceptional digital cursor control for greater speed, accuracy, and reliability.

QuickStick and QuickStick ADB from Kraft Systems, Inc.

-----

QuickStick combines the cursor response of a mouse with the speed and convenience of a joystick. As such, it is a dual-purpose device allowing cursor control with joystick design and functions.

Trackball ADB from Kraft Systems, Inc.

-----  
The Trackball ADB connects to any Apple Desktop Bus port and works with all "mouseable" software. Sensitivity is adjustable to match a user's individual preference. The Trackball includes drag and double-click buttons. An optional foot pedal provides total one-handed control.

Turbo Mouse Plus and Turbo Mouse ADB from Kensington Microware, Ltd.

-----  
Turbo Mouse is an input device that puts the mouse ball on the top rather than on the bottom like a standard mouse. The heart of the Turbo Mouse is a patented technology called "optical leveraging". This opti-mechanical technology eliminates virtually all moving parts with the exception of the bearings required to support the trackball. This increases the precision of the Turbo Mouse and Turbo Mouse ADB to 200 counts per inch, as well as increases their reliability.

The Turbo Mouse has an automatic acceleration feature that senses the speed at which a user is working and moves the cursor further as the mouse ball is moved faster.

Two buttons are included, which allow for either right- or left-handed use. One button serves as a regular click button; the other is a click lock. A user controls which is which by setting a DIP switch hidden in the back of the unit.

Turbo Mouse ADB also offers a unique "chording" feature that is activated by pressing both buttons simultaneously. By adjusting the DIP switch on the back of the Turbo Mouse ADB, a user can have it do one of seven functions: New, Open, Close, Save, Print, Quit, or Undo.

Turbo Mouse Plus is compatible with a Macintosh and Macintosh Plus. Turbo Mouse ADB is compatible with a Macintosh SE and Macintosh II.

## System 6.0.4 Installer: How to Access the Remove Button

Revised: 3/4/90  
Security: Everyone

System 6.0.4 Installer: How to Access the "Remove" Button

=====

This article last reviewed: 29 January 1990

TOPIC -----

The new Installer is great, but it appears to be missing the ability to remove previously installed resources. Will this be fixed?

DISCUSSION -----

That is a great idea and, fortunately, that feature is already part of the "new" Installer, version 3.0 which ships with System Software 6.0.4.

To invoke it, either hold down the Option key while launching the Installer, or after launching the Installer, press Customize, then hold down the Option key. Note that holding down the Option key changes the "Install" button to a "Remove" button. Releasing the button key changes to button back to Install.

## LaserWriter IINTX: Compatible Hard Drives

Revised: 3/4/90  
Security: Everyone

LaserWriter IINTX: Compatible Hard Drives

=====

This article last reviewed: 29 January 1990

TOPIC -----

I am trying to connect a DataFrame XP to a LaserWriter IINTX. It's not working. I noticed that the "Winter Solstice" manual states that some third-party drive won't work if they cannot state their size. Is the DataFrame one of these drives?

DISCUSSION -----

SuperMac Technology reports that the newer DataFrame 20 and XP-30, -60, and -100, all work on the LaserWriter IINTX. These drives have been shipping since March 1, 1989 and have built-in fans and no vents on the top of the housing. Earlier drives don't work, because they don't have embedded SCSI controllers that are able to pass all the parameters from the HDA to the LaserWriter IINTX, which the LaserWriter IINTX requires.

Additionally, Adobe has tested and confirmed that the following drives work with the LaserWriter IINTX:

Seagate ST225N  
Rodime 650 series (R0651, R0652, R0751, R0752)  
Quantum Q200 series (Q250, Q280)  
MiniScribe 8425-SCSI  
MiniScribe 80515

Generally, we have found that only drives using embedded SCSI controllers are compatible. For more information on this topic, see the November 15, 1988, issue of "MacWeek."

## VideoWorks Accelerator: Macintosh IICI Incompatibility

Revised: 3/4/90  
Security: Everyone

VideoWorks Accelerator: Macintosh IICI Incompatibility

=====

This article last reviewed: 30 January 1990

TOPIC -----

I have a Macintosh IICI with System Software 6.0.4, a MacroMind accelerator, and PhotoMac. I get the error message, "System needs the Jackson Pollock software patch or system may not start up". Have you heard of this error?

DISCUSSION -----

Receiving the error message, "System needs the Jackson Pollock software patch or system may not start up", indicates that the application isn't calling 32-Bit QuickDraw properly. Alternatives include not using 32-Bit QuickDraw or obtaining an update from the software manufacturer that corrects this incompatibility.

Some versions of VideoWorks Accelerator aren't compatible with 32-Bit QuickDraw nor with the Macintosh IICI. Running it under these configurations results in the above error message. A revision of Accelerator that fixes this problem is now available. It is free of charge to Accelerator owners on a request basis only.

PhotoMac is reportedly compatible with the Macintosh IICI and 32-Bit QuickDraw.

## A/UX: Shared Memory Error Message (9/94)

Revised: 9/21/94  
Security: Everyone

A/UX: Shared Memory Error Message (9/94)

Article Created: 30 January 1990  
Article Reviewed/Updated: 21 September 1994

TOPIC -----

I am an A/UX developer porting an HP X Window System application using the "Big C" C compiler on a Macintosh IIci with 8MB RAM. The issue is the use of the memory with swapping of shared memory.

I modified the kernel for use of shared memory with:

```
SHMMAX 2097152
SHMSEG 12
```

During the creation of the fifth partition of shared memory, the following message appears:

```
shmget: Not enough space (errno:12)
```

Other information:

```
RAM: 8MB
Swap Space: 49352 blocks.
Size of the segments of shared memory:
```

- 1) 2020 bytes
- 2) 1004664 bytes
- 3) 381536 bytes
- 4) 386536 bytes

Why am I getting this error message? Does A/UX keep the shared memory in RAM?  
Can it not be swapped to disk?

DISCUSSION -----

The key is the "shmget: Not enough space (errno:12)" error message that occurred

during the creation of the fifth segment of shared memory. It means that the available, system-wide, total, shared memory space (in pages) is not large enough to accommodate the shared memory segment to be created. The default maximum system-wide total shared memory size is 512 pages defined in the "shminfo" data structure (shminfo.shmall). The total size of your four shared memory segments is about 433.3 pages.

You may change the default size of "shmall" in the same way you modified for the "shmmax" and "shmseg" using "adb".

Generally, A/UX keeps the shared memory in its virtual address space after doing the "shmget" and "shmat" system calls. The "shmget" system call with the IPC\_CREAT flag creates a new shared memory region, and the kernel verifies the size and allocates a region data structure. Then the kernel saves a pointer to the region table entry in the shared memory table and sets a flag to indicate that no memory is associated with the region. The kernel allocates memory for the region only when a process attaches the region to its address space via the "shmat" system call.

For the shared memory segment not to be swapped to disk, two commands (SHM\_LOCK and SHM\_UNLOCK) can be used in the "shmctl" system call (the shared memory control system call) to lock or unlock the specified shared memory segment into the physical memory. The SHM\_LOCK and SHM\_UNLOCK are defined in the /usr/include/sys/shm.h file.

For information on the shared memory, refer to the shmget(2), shmat(2), shmctl(2), ipcs(1), and ipcrm(1) manual pages.

## AppleTalk: WangNet Gateway Not Yet Available

Revised: 3/4/90  
Security: Everyone

AppleTalk: WangNet Gateway Not Yet Available

=====

This article last reviewed: 17 February 1990

TOPIC -----

I want to connect a LaserWriter directly to a Wang VS system. I also want to maintain Macintosh access to the LaserWriter while doing this.

Is there some way to connect a LaserWriter directly to a Wang VS? If yes, is there some way that Macintosh output can still be directed to the Wang system?

I also have made extensive use of Wang PCs with WangNet in another office, and, consequently, have very few ADCs or EADCs. I want to have access to the Wang systems from the Macintoshes over a network without having to buy dozens of Shiva NetSerials and Wang ADCs (our current solution). Is there anyway to replace the Wang terminals with Macintoshes having a window into the VS world.

Do you know of a WangNet/AppleTalk gateway? Do you have any other suggestions for connecting Macintoshes to a Wang VS without having to purchase ADCs?

DISCUSSION -----

WangNet uses a dual-cable topology and has divided the cable's bandwidth among a number of services: Wang Systems (also called Wang Band) dedicated interconnect services (now Multivendor Services) Utility Band (Utility Service) and the Peripheral Attachment Service. Each WangNet service uses its own set of transmission techniques, each with its own form of access control, its own data transmission rates, and its own place on the network's frequency spectrum. Each also uses its own interfacing hardware.

Though Multivendor Services is an 802.3 service, accessible to Macintoshes with Ethernet cards via their MAUs, as of December, 1989, there was no gateway between the Wang Systems and Multivendor Services. Similarly, there was no WangNet/AppleTalk gateway.

You might consider alternatives like serial connections for file transfers or

terminal emulation. These techniques that are well-documented in the Tech Info Library and in the Apple Multivendor Network Solutions Guide.

One mail gateway is SNADS Gateway/MSMail from SoftSwitch, Inc. This product lets Microsoft Mail 2.0 users exchange files with users of Wang Office, DISOSS, PROFS, ALL-IN-1, and Hewlett-Packard Desk.

For more details, search the Tech Info library under "SNADS."

## Macintosh: Data Aquisition, Analysis, and Display

Revised: 3/4/90  
Security: Everyone

Macintosh: Data Aquisition, Analysis, and Display

=====

This article last reviewed: 17 February 1990

TOPIC -----

I want a package that can pull information directly from an oscilloscope and graph it so that the chart can later be integrated into a Macintosh word processing document. I know of National Instruments' products, but they aren't appropriate for my application. Do you have any alternatives?

DISCUSSION -----

We searched the Macintosh Buyer's Guide on AppleLink and found two companies that may be able to help.

Ansan Industries, Ltd's MacScope

-----  
MacScope from Ansan Industries, Ltd. is a turnkey data-acquisition system that combines the measurement capability of Gould's model 1425 Digital Storage Oscilloscope with the high-resolution graphics and user interface of the Macintosh. Desktop engineering and desktop publishing are combined in a system that can handle data acquisition and presentation tasks. MacScope can do in-depth computation and analysis and generate presentation graphics or technical documents. Data is captured at two samples to two megasamples per second for one-shot events. Repetitive waveforms can be stored with a 20MHz bandwidth in the equivalent time mode.

Spectral Innovations' MacDSP24MC and MacDSP16K

-----  
Spectral Innovations' MacDSPSW-002 is an interactive signal-processing package that offers real-time spectral and time analysis, filtering, modulation, and other signal processing techniques at a mouse click. This lets you see effects on processed data immediately.

Analog and digital signals are sampled at up to 1MHz using Spectral

Innovations' data-acquisition expansion cards. Sampled signals are instantly processed by the MacDSP signal processing card with screen updates 20 times per second. Real-time color displays include oscilloscope, spectrum analyzer, waterfall, spectrogram, and three-dimensional contour graphs.

For more details, search the Tech Info library under "Ansan Industries" and "Spectral Innovations."

## HyperCard: Fix for DateBook Stack

Revised: 6/24/90  
Security: Everyone

HyperCard: Fix for DateBook Stack

=====

This article last reviewed: 17 February 1990

TOPIC -----

I found a problem in HyperCard's DateBook stack. The DateBook stack updates itself from January to June with the new dates for 1990. Then, when I click on the first week of January, it asks if I want to update the weekly calendar, and I answered yes. After finishing this, I went to the Home card and clicked on the Calendar icon again and then on the first week. At this point, nothing happened. If I click on week 2, it works perfectly, and I get the weekly calendar for the second week. Can you explain?

DISCUSSION -----

There are the two minor changes you need to make to avoid this problem, part of which has to do with backgrounds. Note to long-term users: This problem will occur again in 2001 and 2018 and every 11 and 16 years afterward:

In the DateBook's stack script, change the "goweekly" handler from this:

```
set lockScreen to true
find startOfWeek(myDate) in bkgnd field "WeekSecs"
```

To this:

```
set lockScreen to true
go bg "Weekly"
find startOfWeek(myDate) in bkgnd field "WeekSecs"
```

Also, in the stack script, change the GoSixMonthly handler from this:

```
visual effect zoom open
find thisHalfYear(myDate) in bkgnd field "MySecs"
```

To this:

```
visual effect zoom open  
go bg 1  
find thisHalfYear(myDate) in bkgnd field "MySecs"
```

These changes will solve both the problem of not going anywhere when you click on the first week in January and the "can't understand bracketweek" message.

## Macintosh IICI: Use Rev D.2 of NB-GPIB Card

Revised: 7/9/92  
Security: Everyone

Macintosh IICI: Use Rev D.2 of NB-GPIB Card

Article Created: 17 February 1990  
Article Last Reviewed: 8 July 1992  
Article Last Updated:

### TOPIC -----

National Instruments' NB-GPIB card is slot-dependent and needs to be stationed in slot 3. The card works fine in a Macintosh IICx, but on the Macintosh IICI, the slot appears to be slot 6 to the application software. Is there any way around this?

### DISCUSSION -----

According to National Instruments, the NB-GPIB card is not slot-dependent and works without any problem in the Macintosh IICI. However, an early revision of this card (Rev D.1) had a compatibility problem with some systems. The problem was with one noise logic chip on the card, the AS02 at card location U19. The Rev D.2 NB-GPIB cards have an LS02 at location U19.

You can exchange the Rev D.1 card with National Instruments for a card that have the LS02 installed. Or, you can upgrade a Rev D.1 NB-GPIB card to Rev D.2, by changing the IC at U19 from the AS02 to an LS02. However, users who change the chip will void the warranty on the NB-GPIB card.

Note: when running the NB-GPIB card test utility, the card may show a failure, depending on the version of the software used. Below is a listing of the software revisions.

## AppleShare PC: Memory Solution

Revised: 3/4/90  
Security: Everyone

AppleShare PC: Memory Solution

=====

This article last reviewed: 17 February 1990

TOPIC -----

Can you recommend a memory expansion card for MS-DOS machines that makes memory available after AppleShare PC 2.0 loads?

DISCUSSION -----

The HiCard from RYBS Electronics is a PC/XT/AT/386 memory card and software that lets MS-DOS machines have more memory available after AppleShare PC 2.0 is loaded. In fact, it leaves as much as 546K on XTs and more on ATs). It is called the HiCard from RYBS Electronics.

There is a HiCard memory cards for PC, XT, AT, 386, and MicroChannel DOS computers. It extends memory but not in the usual fashion. Most memory cards add Extended Memory or Expanded Memory (LIMM), but problems exist, because many DOS applications cannot make use of these types of memory. HiCard adds additional conventional memory, which can be used by most DOS applications, device drivers, and RAM-resident utilities. Software comes with the card to load the device drivers that make the extra memory work. In addition, you can also add AMS (HiMem) memory and Expanded memory.

The product works by taking advantage of the available address space between 640K and 1MB in MS-DOS computers. They state that this area in RAM is usually reserved for ROM BIOS, video adapters, and network cards, and that the RAM space is never completely used. Thus, they can extend usable memory to 736K (total DOS) on a PC, with an additional 256K for AMS memory. RAM-resident utilities and device drivers can be loaded into memory above 736K (AMS memory), thus freeing conventional memory for applications. According to RYBS, you can put BUFFERS, FILES, LASTDRIVE, and other DOS device drivers and TSRs into high memory as well.

Our system consisted of a 640K XT-compatible from CompuAdd and the HiCard board containing 256K RAM running MS-DOS 4.0 and AppleShare PC 2.0.

We loaded AppleShare PC with the desk accessory RAM resident. One AppleShare File Server volume was automatically mounted as the D: drive on the PC. With 640K total RAM, the CHKDSK program showed 655K total memory, and 313K remaining (one other unrelated RAM-resident utility was loaded at startup).

I tried to mount another AppleShare File Server as the E: drive. The Chooser interrupted with the error message, "Not enough memory" and the second volume would not mount.

I installed the HiCard. After running the configuration program, setting DIP switches, and installing the card, a CHKDSK showed 720K available, with 626K free.

I was then able to mount a second file server volume as drive E:, and a third as F: with no problems.

Here's a chart outlining memory use before and after the HiCard was installed:

- Before HiCard:

|                                           |                             |
|-------------------------------------------|-----------------------------|
| Normal DOS boot                           | 561K RAM remained available |
| Boot with AppleShare and the DA<br>in RAM | 313K RAM remained available |

- After installing HiCard and software:

|                                                                                      |                             |
|--------------------------------------------------------------------------------------|-----------------------------|
| DOS boot                                                                             | 626K RAM remained available |
| Boot with AppleShare PC, DA in RAM,<br>and as much as possible in High Memory        | 546K RAM remained available |
| Boot with AppleShare PC, DA NOT in<br>RAM, and as much as possible in<br>High Memory | 599K RAM remained available |

Presumably, this extra memory also could have been used for application space, so I tested it by running Lotus 1-2-3, exiting to the DOS shell, and running WordPerfect. Exiting to the DOS shell left 192K available, and WordPerfect launched fine in this memory.

The manufacturer also claims that their card and software work with Banyan, StarLAN, 3COM, DCA 10Net, IrmaLAN, PCSA, Novell, PC-NFS, TOPS, Token Ring, and other networking cards. We were unable to test the card in these scenarios.

The CompuAdd PC we used for testing did have a few minor compatibility issues. However, the excellent technical support from RYBS helped us to work around the problems.

Here are the hardware and software switches that worked on the CompuAdd PC:

DIP Switches:

All ON except: 1 OFF 5 OFF 7 OFF 8 OFF

Autoexec.bat: (Note: The Moremem line is particular to each machine and configuration):

## System 6.0.4: Installer Problem with Duplicated Disks

Revised: 3/4/90  
Security: Everyone

System 6.0.4: Installer Problem with Duplicated Disks

=====

This article last reviewed: 17 February 1990

TOPIC -----

I copied all of System 6.0.4 files from the original disks to a server. I then copied all the appropriate files back to blank disks, so that they mirrored the original disks. However, when I tried to use the Installer with these new disks, the Installer did not work. I did a disk-to-disk copy of the original disks to the blank disks, and the Installer did work. Can you explain?

DISCUSSION -----

We were able to use the Installer successfully from a set of disks created in the manner you describe. The steps we used to copy each disk are:

- 1) Copy the Installer disk to the server volume by dragging its icon to the server volume's icon or window. Confirm the "The two disks are different types..." dialog by clicking OK. A new folder is created on the server volume with the Installer disk's name and files.
- 2) Open the newly created folder.
- 3) Insert a blank 800K disk and name it exactly the same as the original. This should be the same name as the folder you opened in the previous step.
- 4) Copy all items from the opened folder (in step 2) to the new disk by dragging them to the disk's icon or opened window. Do not copy the entire folder--only the files and folders within it.

The Installer can become confused and not recognize a seemingly valid Installer disk if you move files between folders or remove files or folders. It is important to make nearly exact duplicates of the Installer disks, with no changes in disk, folder, or filenames. As you experienced, a disk-to-disk copy is a reliable way to make duplicates.

## Metric Tools: Phillips Heads

Revised: 3/4/90  
Security: Everyone

Metric Tools: Phillips Heads

=====

This article last reviewed: 27 December 1989

Eiki, a major manufacturer of school projectors is an excellent source for metric tools and screws, including Phillips heads. Most Apple equipment manufactured overseas (like the LaserWriter II engine) uses metric screws. The standard American Phillips drivers tend to strip out the heads of metric Phillips screws.

Eiki has a neat little tool kit that includes a #1 and #2 Metric Phillips for a suggested retail price of \$13.00. The part number is AC-85311

They have a dealer distribution network and you can find the nearest Eiki dealer by calling (714) 831-2511

## A/UX: Big C Compiler Error Message--too many defines

Revised: 9/15/92  
Security: Everyone

A/UX: Big C Compiler Error Message--"too many defines"

=====

Article Created: 27 December 1989

### Article Change History

-----

08/31/92 - REVIEWED

- For technical accuracy

### TOPIC -----

My Big C compiler who gives the "too many defines" error message. How can I raise the number of usable arguments/functions?

### DISCUSSION -----

The error message "too many defines" that occurred while compiling with the Big C compiler indicates that too many #define directive statements were defined in the C source program. This error message was detected by the "cpp", the C PreProcessor, while compiling the C source file. Currently, the maximum number of the #define directives defined by the Big cpp in A/UX 1.1 is around 2000. These numbers are used for the #define variable memory allocation.

We have tested a simple C program (with about 1985 #define directives) compiled under the Big C compiler of an 8MB A/UX 1.1, and the Big cpp complained with the same "too many defines" message.

To prevent this problem, reduce the number of #define directives in each C source file.

## A/UX: Apple Outline Fonts and the toolboxdaemon (8/95)

Revised: 8/7/95  
Security: Everyone

A/UX: Apple Outline Fonts and the toolboxdaemon (8/95)

=====

Article Created: 4 March 1990  
Article Reviewed/Updated: 7 August 1995

TOPIC -----

Can I use Apple Outline Fonts in A/UX 1.1 without the toolboxdaemon running?  
That is, can I put the routines in libraries?

DISCUSSION -----

Support for any of the Macintosh Toolbox features under A/UX requires the use of the toolboxdaemon. Essentially, the toolboxdaemon provides the equivalent of the libraries you are referring to. Without the complete Macintosh environment available, none of the Macintosh calls would function.

Furthermore, A/UX 1.1 and A/UX 1.1.1 do not support Outline Fonts or any of the new technology target areas as specified in the documentation that has been released about the new Macintosh System Software directions. This means that the underlying Font Manager necessary to use Outline Fonts is not available even if the toolboxdaemon is running.

A/UX 2.0.1 supports the Adobe Type Manager.  
A/UX 3.0 fully supports System 7 TrueType outline fonts.

## IBM TCP/IP for VM and MVS and the InterLink NFS Server

Revised: 4/30/90  
Security: Everyone

IBM TCP/IP for VM and MVS and the InterLink NFS Server

=====

This article last reviewed: 27 December 1989

TOPIC -----

This article describes IBM TCP/IP for VM, IBM TCP/IP FOR MVS, and InterLink's products.

DISCUSSION -----

### 1) IBM TCP/IP for VM:

IBM TCP/IP for VM is a program that operates on a 9370, 43XX, or 30XX to provide the VM user with the capability of participating in a network that uses the TCP/IP protocol. This participation includes the ability to transfer files, send mail, and log on to a network-connected system or host.

TCP/IP for VM uses an S/370 channel to attach to a variety of controllers for connection to the selected network. It supports these network controllers:

- a) LAN Channel Station (8232)
- b) Series/1 with Real Time Programming System

### Highlights

-----

IBM TCP/IP for VM includes

- File transfer using FTP (File Transfer Protocol).
- Access to IBM 3270 applications from workstations using Telnet 3270 protocols.
- Remote terminal access using the Telnet protocol to access multivendor hosts.
- Compatibility with IBM Token Ring, IBM PC, Ethernet, ProNet, or X.25 networks.

#### Additional Features

-----

IBM TCP/IP for VM also has

- Network File System Feature (Server). NFS enables the VM system to act as a file server for vendor systems that have the NFS 3.2 client function installed. Does not include the NFS Client function. This NFS feature also includes Remote Procedure Call (RPC). Both the NFS and RPC protocols adhere to the External Data Representation (XDR) specification so that protocols can be independent of internal machine formats.
- 9370 Integrated X.25 Subsystem (driver)
- CMS X Window System (client) (Version X.11)
- Remote Execution Daemon (server)
- SNA Network Link
- HYPERchannel support (driver)

### 2) IBM TCP/IP FOR MVS:

As with TCP/IP for VM, this program operates on a 9370, 43XX, or 30XX to provide the MVS user with the capability of participating in a network that uses the TCP/IP protocol.

In addition to the network controllers supported by TCP/IP for VM, this program also supports the 37x5 Communications Controller (X.25).

#### Highlights

-----

IBM TCP/IP FOR MVS has the same features as TCP/IP for VM, plus:

- Electronic mail to remote terminals using a TSO user interface to the Simple Mail Transfer Protocol.
- C and Pascal subroutine interface to TCP and UDP.

As with TCP/IP for VM, this program also supports:

- Network File System (NFS) Feature (Server)
- Network connections via SNA or X.25 (including DDN)
- X Window System client function

### 3) InterLink

InterLink implements DECnet as an application under the IBM MVS and VM operating systems. The IBM host becomes a peer node in the DECnet environment allowing transparent communications between IBM and DECnet networks. InterLink's evolving product line includes support for multiple protocol (SNA, DECnet, TCP/IP) connectivity applications.

InterLink and Sun Microsystems jointly developed MVS-based NFS services for the UNIX networking environment. InterLink NFS/Connect software coupled with Sun's specialized IBM channel-connected workstation offer record-level data access to data stored on IBM MVS

operating environments.

## A/UX: Drive Corrupted when Copying Disk (8/94)

Revised: 8/25/94  
Security: Everyone

A/UX: Drive Corrupted when Copying Disk (8/94)

Article Reviewed/Updated: 24 August 1994

TOPIC -----

I just copied an external HD80 SC (SCSI ID=2) loaded with A/UX onto an internal HD80 SC on a Macintosh IIX with the following command:

```
dd if=/dev/rdisk/c2d0s31 of=/dev/rdisk/c0d0s31 bs=24576
```

After approximately 15 minutes, the prompt returned with a message giving the number of blocks transferred. When I tried to restart the machine, I found the internal drive is corrupted. All I get on startup is the disk with the flashing question mark.

I tried to clear the internal drive with both HD Setup and Disk First Aid, and none worked. The returned messages are "Unable to read the required table from the selected", or "Fail to read the table".

If I start up the machine using the external A/UX drive, I'm able to mount the internal A/UX partition (SCSI-0) using the following command:

```
mount -v /dev/dsk/c0s0s31 /tmp
```

Can you help me fix the corrupted table on my internal A/UX drive?

DISCUSSION -----

To ensure disk integrity when copying from one disk to another, we suggest the following:

1) Do a "fsck" on the source disk to make sure the original disk file system is good.

2) Use bs= multiple of k (1024 bytes) or b (512 bytes block) rather than the number of bytes on the "dd" command. The bs=24576 is actually bs=24k or bs=48b, which is fine because it is a multiple of 512 bytes.

Are you sure you gave this number? If the number is not a multiple of 512, it could create a corrupted A/UX disk, because the A/UX file system requires a 512-byte block or 1024-byte boundary.

3) Do a "fsck" on the newly-created disk to ensure that the target disk file system is good.

We don't think that there is a way you can correct the corrupted file system, if the created or "dd" file system's block size was not a multiple of 512 bytes.

It is not clear how the error messages "Unable to read the required table from the selected" or "Fail to read the table" was generated. Which step of HD Setup ("Initialization", "Update", or "Partition") encountered these messages?

It is unusual to mount the entire disk /dev/dsk/cXd0s31 on a directory. If you do a "mount -v /dev/dsk/c0d0s31 /tmp", you will get the error message:

```
mount: /dev/dsk/c0d0s31 on /tmp: Invalid file system
```

Just a reminder, by default:

```
/dev/[r]dsk/cXd0s0   is for Root&Utr file system
/dev/[r]dsk/cXd0s1   is for Swap file system
/dev/[r]dsk/cXd0s2   is for Utr file system
/dev/[r]dsk/cXd0s31  is for entire disk
```

We don't mount Swap file system and entire disk.

Can you see the internal disk partition map using "dp" under A/UX?

Last, we suggest that you use HD Setup to "Initialize" the internal hard disk, and follow the above suggestions to clone the disk.

## ADB Keyboard: Problem with Function Keys When Emulating VT240

Revised: 8/23/91  
Security: Everyone

ADB Keyboard: Problem with Function Keys When Emulating VT240

=====

Article Created: 4 March 1990  
Article Last Reviewed: 23 August 1991  
Article Last Updated: 23 August 1991

TOPIC -----

I am having problems using VT240 terminal emulators with Macintosh SEs with Apple SuperDrives (formerly Apple FDHD) and extended keyboards. The problem is that I can't use some function keys (PF2, PF3, and PF4), like the six keys above the arrow keys on the extended keyboard.

It seems to be a CPU-related problem, because I have tried all the possible combinations between the old and the new extended keyboard, reinstalled system software 6.0.3, and used the latest revisions of the two emulators (VersaTerm Pro and Mac240). I have problems only when using the Macintosh SEs with SuperDrives. Everything works fine with older CPUs.

What's going on?

DISCUSSION -----

We tested Mac240 on our Macintosh SE with a SuperDrive, and the function keys are working exactly the same as on the Macintosh SE with 800K drive.

According to page 82 in Appendix A of the Mac240 manual, DEC keyboard keys F1-F5 are not present on the ADB keyboard. These keys perform local functions on a VT240 terminal (Hold Screen, Print Screen, Setup, DataTalk, and Break). Equivalent operations are available in Mac240 menus. DEC keyboard F6 and up are mapped to ADB keys F1 and up as follows:

| DEC Keyboard | ADB Keyboard |
|--------------|--------------|
| -----        | -----        |
| F1-F5        | Not Present  |
| F6           | F1           |

|      |     |
|------|-----|
| F7   | F2  |
| F8   | F3  |
| F9   | F4  |
| F10  | F5  |
| F11  | F6  |
| F12  | F7  |
| F13  | F8  |
| F14  | F9  |
| Help | F10 |
| Do   | F11 |
| F17  | F12 |
| F18  | F13 |
| F19  | F14 |
| F20  | F15 |

Pressing the F1 key on the ADB keyboard is equivalent to pressing the F6 key on the VT240, which happens to be Control-C, the CANCEL key. Pressing F10 and F11 on the ADB keyboard is like pressing the Help and Do keys on the DEC keyboard. This was verified using DEC Edit/TPU program.

The six keys above the arrow keys on the ADB keyboard also worked correctly for us on the Macintosh SE with the SuperDrive and with the 800K drive. Keep in mind that they do not have the same meanings as their labels. They work like the DEC keyboard labels:

| DEC keyboard | ADB keyboard |
|--------------|--------------|
| -----        | -----        |
| Find         | help         |
| Insert Here  | home         |
| Remove       | page up      |
| Select       | del          |
| Prev Screen  | end          |
| Next Screen  | page down    |

One other thing to check is to make sure that the terminal is set correctly on the host machine as VT200 series. On VAX/VMS, use the command:

```
$ SET TERMINAL/DEVICE=VT200
```

## Macintosh IIcx & IIci: 5.25-Inch Internal Hard Disk Installation

Revised: 6/18/92  
Security: Everyone

Macintosh IIcx & IIci: 5.25-Inch Internal Hard Disk Installation

=====

Article Created: 19 February 1990  
Article Last Reviewed: 18 June 1992  
Article Last Updated:

TOPIC -----

I want to purchase third-party (MicroNet) 5.25-inch hard disks with special mounting brackets for my Macintosh IIcx and Macintosh IIci systems.

- 1) What is Apple's position about using 5.25-inch drives in the Macintosh IIcx or Macintosh IIci?
- 2) Will these drives draw too much power?

DISCUSSION -----

- 1) Apple's position is that the installation and use of an internal 5.25-inch hard disk in a Macintosh IIcx or Macintosh IIci voids the warranty of the computer.
- 2) An internal hard disk may draw 1 amp (5 watts) on the +5V line and .5 amps (6 watts) on the +12V line. On startup, a surge of 1.5 amps (18 watts) for 15 seconds is allowable on the +12V line. No surge is allowed on the +5V line.

## Macintosh IIci: ROMs Are for IIci Only

Revised: 7/9/92  
Security: Everyone

Macintosh IIci: ROMs Are for IIci Only

=====

Article Created: 19 February 1990  
Article Last Reviewed: 8 July 1992  
Article Last Updated:

TOPIC -----

I heard that the Macintosh IIci ROMs can be put into a Macintosh IICx or Macintosh SE/30 to improve performance. Is there any truth to this?

DISCUSSION -----

The Macintosh IIci ROMs have been tested only in the Macintosh IIci. They may work properly in the Macintosh IICx or Macintosh SE/30, but there would be no perceptible improvement in performance. Using the Macintosh IIci ROMs would not cause the Macintosh IICx or Macintosh SE/30 to support the "burst mode" abilities of the MC68030 microprocessor. The Macintosh IIci and the Macintosh IIfx are the only Macintosh computers that have the hardware to support the "burst mode". We do not support using the Macintosh IIci ROMs in a Macintosh IICx or Macintosh SE/30.

## Macintosh SE: Correcting Hierarchical Menu Delay

Revised: 8/7/92  
Security: Everyone

Macintosh SE: Correcting Hierarchical Menu Delay

=====

Article Created: 4 March 1990  
Article Last Reviewed: 6 August 1992  
Article Last Updated: 23 August 1991

TOPIC -----

I have a Macintosh SE with a 20MB hard disk, the Apple SuperDrive (formerly Apple FDHD), and 1MB of memory. I have the basic fonts and DAS that come with the system. When I select a menu item that has a hierarchical menu attached, the hierarchical menu takes about 4 to 6 seconds to appear. I've tried:

- Programming on another Macintosh, and it worked fine.
- I used an application on the hard drive and then tried using the same program from a floppy disk. It still had the same problem.
- Reinstalling system software 6.0.3; the delay remained.
- Reformatting the hard drive and reinstalling everything--same result.
- Running SAM. No viruses were found.
- Removing nonstandard INITs from my System Folder.
- Setting up 64K and 96K RAM caches--neither had any effect on the delay.
- A technician ran Apple diagnostics tests on the computer, and it passed without a problem.

Can you help?

DISCUSSION -----

There is a parameter in extended PRAM that controls how long a menu item

must be selected before the hierarchical menu for that menu item appears. We suggest zapping extended PRAM by holding down the Shift, Option, and Command keys while opening the Control Panel. Restart the computer when the procedure is done. This resets the delay to the default value, and the hierarchical menu delay problem should disappear.

## PostScript: Macintosh and Sun Codes Are Different

Revised: 3/4/90  
Security: Everyone

PostScript: Macintosh and Sun Codes Are Different

=====

This article last reviewed: 19 February 1990

TOPIC -----

Does Sun use the same version of PostScript as the Macintosh for printing? If yes, is there a way to use Sun documents on a Macintosh?

DISCUSSION -----

There are differences between the actual PostScript code generated on the two different computers.

On the Macintosh, the PostScript code created relies on the Laser Prep dictionary. This means that there are many short codes in a Macintosh PostScript file that relate the Laser Prep dictionary. On the Sun machines, PostScript is generated as complete (sometimes called "raw") PostScript.

However, it is possible to move an EPS (Encapsulated PostScript) file from the Sun environment to the Macintosh environment. The ability to create and read an EPS file is application-dependent. An EPS file created in a Sun application can be moved to a Macintosh and read by a Macintosh application supporting the EPS file format.

Generally, a Sun EPS file will not display on the Macintosh screen but will print fine on PostScript printers. Most Macintosh applications present such a screen display as an empty area with a border. However, Macintosh application, like LaserTalk, can display the image defined by PostScript because the image is only a screen representation of PostScript code.

## AppleFax Modem: FaxGate Allows Some Networking Capability

Revised: 3/4/90  
Security: Everyone

AppleFax Modem: FaxGate Allows Some Networking Capability

=====

This article last reviewed: 15 January 1990

QUESTION -----

Does anyone have any suggestions for a "networkable" AppleFax Modem?

RESPONSE -----

The AppleFax Modem and AppleFax software was not designed for use in a Fax server environment. You might take a look at Solutions International's FaxGate. It lets a Macintosh send a message to a second Macintosh with a locally-connected AppleFax Modem via QuickMail or Microsoft Mail. The sending Macintosh, running FaxGate in the background, transmits the message over the AppleFax Modem. Note that this product is for transmitting Fax messages, not receiving them.

## A/UX: lint Problems (9/94)

Revised: 9/21/94  
Security: Everyone

A/UX: lint Problems (9/94)

=====

Article Created: 27 December 1989  
Article Last Reviewed: 21 September 1994

TOPIC -----

I have found four problems with lint:

1) The -o option generates the following error:

```
/usr/lib/lint1: illegal option -- o
```

2) The manual does not explain how to create the "llib-lx.ln" file in the "-lx" option.

3) In this line, the -Dlint does not get defined:

```
cc -E -C -Dlint llib-lx | /usr/lib/lint1
```

4) There is no way to tell lint where to look for Lint libraries.

DISCUSSION -----

A couple of lint problems have been found and reported in the A/UX Engineering SPR database. These include that

1) The -o option is not implemented in A/UX 1.1. However, it is implemented in 2.0, 2.0.1, and 3.0.

2) The commands below described in the -lx option of lint(1) to generate the llib-lx.ln from the llib-lx were not correct; "cc" expects a C source file.

```
cc -C -C -Dlint llib-lx | \  
/usr/lib/lint1 -vx -H/tmp/lint$$ > llib-lx.ln  
rm -f /tmp/lint$$
```

The purpose of the -lx option is to include an additional lint library, (named llib-lx.ln) in the /usr/lib directory to be searched. For example, the -lm for additional search on the mathematical lint library, /usr/lib/llib-lm.ln. There is a naming error on the /usr/lib/llib-port.ln; it should be named /usr/lib/llib-lport.ln for the portable C lint library.

## A/UX: Sorting Large Indexes (9/94)

Revised: 9/22/94  
Security: Everyone

A/UX: Sorting Large Indexes (9/94)

=====

Article Created: 4 March 1990  
Article Reviewed/Updated: 22 September 1994

TOPIC -----

Is there any known A/UX-based software for sorting large indexes (20-40MB)?

DISCUSSION -----

We aren't sure what you mean by "large indexes". A/UX includes the standard "sort" command, which is able to sort lines from one or more files. The maximum number of lines it can sort is limited only by disk space. If your needs go beyond sorting lines, you should investigate a database manager of some sort. Check with Oracle Corporation and Informix Software for information on their products (For more details, search the Tech Info Library under "Oracle" and "Informix.")

A/UX: Using Northern Telecom Memorybank

=====

Article Created: 15 January 1990

### Article Change History

-----

08/31/92 - REVIEWED  
• For technical accuracy.

### TOPIC -----

Will A/UX run on the Northern Telecom Memorybank? Can it access the  
Memorybank's tape drive?

### DISCUSSION -----

Yes, the Northern Telecom Memorybank works with A/UX. Northern Telecom provides configuration software to prepare their drive for use with the Macintosh OS, A/UX, or both. They also provide backup software that can do fully-automated backups to tape under the Macintosh OS and an advanced A/UX driver for their tape drive for traditional file backups under A/UX. For more information, search the Technical Info library under "Northern Telecom".

## TokenTalk: Sniffer MisReads AARP

Revised: 3/4/90  
Security: Everyone

TokenTalk: Sniffer MisReads AARP

=====

This article last reviewed: 4 January 1990

TOPIC -----

Why does Sniffer see AppleTalk as a standard IBM Token Ring hardware and then as an Ethernet type=80F3? During the time I ran my tests, one of my PC LAN servers crashed in a big way, and I wonder if the TokenTalk card and software might have contributed to its demise.

DISCUSSION -----

The Sniffer is displaying the AppleTalk Address Resolution Protocol (AARP). AARP performs three basic functions:

- It initially determines the unique protocol address of an AppleTalk node for a given protocol set (like the AppleTalk protocols).
- It maps between two address sets.
- It filters packets within a given protocol set.

In AppleTalk Phase 2, AARP packets are encapsulated in IEEE 802.2 format on data links that support this standard. To accommodate the large number of protocols, IEEE developed the SubNetwork Address Protocol (SNAP) standard. The SNAP allows multiple protocols to be used in one data link. It defines a 5-byte field to identify the protocol that is using the data link. It ensures that protocol identifiers from different vendors do not conflict. The SNAP protocol discriminator for AARP packets is \$00000080F3; the Sniffer mistakenly reported this as Ethernet.

Nevertheless, these packets should not cause the LAN server to crash. We connected a Sniffer to a Token Ring LAN in our office and also saw these SNAP packets reported incorrectly, but the server and the network are operating normally.

We strongly suggest that you upgrade to the latest version of software. You must use the new 1.1.2 version of Apple File Exchange with SMB and TokenTalk 2.0 final.

## GS/OS 5.0.2: Solves No Finder Printing Problem

Revised: 3/4/90  
Security: Everyone

GS/OS 5.0.2: Solves "No Finder" Printing Problem

=====

This article last reviewed: 4 January 1990

TOPIC -----

I have a problem on my Apple IIGS lab (LocalTalk and GS/OS 5.0 with the current version of Aristotle) when I start from Aristotle on disk, bypassing the Finder. I log on and run Chooser.II from Aristotle to choose an ImageWriter. When I try to print from AppleWorks or various MECC applications nothing happens.

For the lab to function in an orderly manner, students need to start from disk and be able to choose a printer. Do you have a workaround? Also, just what file is it that holds the name of the chosen printer?

DISCUSSION -----

Upgrading to GS/OS 5.0.2 resolves this issue. This version of GS/OS, when used with the "No Finder" startup disk, defaults to the user's assigned printer set in the AppleShare Admin program.

When using GS/OS 5.0.2, you needn't use Chooser.II to make network printer choices. If you use a Finder startup disk, the Control Panel provides the printer choice via the various printer Control Panel devices. With a "No Finder" startup disk, the printer choice is made in AppleShare Admin's Apple II menu. When starting up across the network, the printer choice is also made in the AppleShare Admin program.

However, if students must dynamically change the printer they use, Chooser.II is required in the "No Finder" and network startup procedures. When running Chooser.II from the server, the printer selection is stored in the ATINIT file located in "USERS/(user's logon name)/ATINIT" on the server. This overrides the choice in the AppleShare Admin setup during this signon. After the user signs off and back on in these two startup procedures, the default printer will be the one set in the AppleShare Admin setup.

Should the desired results be "one student assigned to one printer," then GS/OS 5.0.2 smoothly handles this situation by using the AppleShare Admin setup during a "No Finder" startup.

## GS/OS 5.0.2 Solves No Finder Problem

Revised: 3/4/90  
Security: Everyone

GS/OS 5.0.2 Solves "No Finder" Problem

=====

This article last reviewed: 15 January 1990

TOPIC -----

I just updated my server to GS/OS 5.0.1 and created startup disks with no Finder to speed startup. The workstations started up and ran applications, but they don't print. Is there a fix for this problem?

DISCUSSION -----

Installing GS/OS 5.0.2 will resolve the problem encountered with the "No Finder" startup disk.

Note: GS/OS version 5.0.1 is NOT a released version of GS/OS. Copies were sent to the Apple SEs, but it has never been officially released. GS/OS 5.0.2 is the official release of the operating system for the Apple IIGS.

## A/UX: Find, Dump & Print an 8-Bit Window w/ X Windows (9/94)

Revised: 9/9/94  
Security: Everyone

A/UX: Find, Dump & Print an 8-Bit Window w/ X Windows (9/94)

=====

Article Created: 27 December 1989  
Article Reviewed/Updated: 9 September 1994

TOPIC -----

I have been trying under X Windows to find and dump an 8-bit window as described in the "README" file under usr/lib/X11. If you set the window plane to the normal white and dump it, the xpr routine seems to work fine. However, if you set the background to a color (like solid blue with yellow text), and you bring back the window with the xwd routine and print it with xpr, you get a blank page.

I assumed that I had not found the proper plane, but I tried many parameters and could not get it to print. Can you give me an example to show how it works?

DISCUSSION -----

We successfully used xwd, xwd and xpr to print both 1-bit and 8-bit windows on a LaserWriter. We also used the plane option of xwd to specify bit planes of xy format dump files. Here are the steps we followed:

- 1) On our 8-bit screen, we created an xterm window with a blue background and a yellow foreground (text), cursor, and pointer.

```
xterm -bg blue -fg yellow -cr yellow -ms yellow &
```

- 2) We dumped the xterm window to the file dump.xy with the xwd command.

- 3) We used the xy option to print to our non-color LaserWriter in the next step.

```
xwd -xy -out dump.xy
```

- 4) To print the dumped image, we used the xpr command with the output piped to our LaserWriter. The "device ps" option dumps the image in a PostScript bitmap. We added the rv (swap foreground and background

colors) option to prevent a white on black image.

```
xpr -device ps -rv dump.xy | atprint
```

- 5) To display the dumped file on screen, we used the `xwud` command. The `raw` option greatly speeds up the display operation.

```
xwud -in dump.xy -raw
```

- 6) To display a specific plane of the file, we used `xwud` with the `plane` option, and a second monitor set to 1 bit. The `plane` option accepts a value in the range of 0 to 7.

```
xwud -in dump.xy -plane 0 -display :0.1
```

## AppleFax-to-AppleFax Communication

Revised: 3/4/90  
Security: Everyone

AppleFax-to-AppleFax Communication

=====

This article last reviewed: 4 January 1990

TOPIC -----

I have tried file transfers between two AppleFax Modems using communications software at 9600 baud. I tried Microphone II to Microphone II and MacTerminal 2.3 to Microphone II. In all cases, I was given error messages or found the system hung. Why is this happening?

DISCUSSION -----

After some extensive testing, we concluded is that you are better off using the AppleFax application for file transfers instead of using third-party terminal software. Third-party software does work, but it is much slower.

The AppleFax Modem has built-in error correction, rendering the error correction performed by MicroPhone, Red Ryder, MacTerminal, and so on redundant. Furthermore, adding those additional layers of protocols and error correction on top of the built-in error correction slows your transmissions down and potentially subjects you to timeout errors (which is probably what you are encountering), compounded by any noise on the lines.

For example, transmitting a .5MB file with the AppleFax application required approximately 14 minutes. Transmitting that same file using MicroPhone II 2.0 using their YMODEM/MacBinary Protocol Transfer Setting was stated by the program's status screen to require over 400 minutes! (Transmitting the same file using YMODEM-G would take approximately 3 hours.)

We didn't wait the nearly 7 hours to verify that it would take that long, because that status screen has been relatively accurate in the past. We did, however, monitor the file transfer for 20 minutes and multiplied the remaining number of bytes to be transferred by the transfer rate. We observed the extremely slow transfer rate and are convinced it would take a very long time. During the 20 minutes we monitored the file transfer, there were no errors reported, nor were there any errors reported with the numerous other small

files we transferred using many of the other MicroPhone transfer settings. Though the files transferred successfully, the file transfers took much longer than when using the AppleFax software.

If you want to continue using MicroPhone or MacTerminal, we recommend using YMODEM-G or MacBinary, respectively, as they do error correction less often than the other options and don't use the other additional error correction options, like CRC.

## CD-ROM: Pre-Press Considerations

Revised: 3/4/90  
Security: Everyone

CD-ROM: Pre-Press Considerations

=====

This article last reviewed: 15 January 1990

TOPIC -----

What can you tell me about storing text information on CD-ROM in High Sierra format and having retrieval engines that will allow access to the data from both MS-DOS and Macintosh platforms.

How does one go about mastering a disc like this? What are the pressing criteria? In what format does the data need to be supplied? How does one maintain Finder file attributes for applications/files in High Sierra? What quirks are there with this process and what information and tools do local pressing agents need?

DISCUSSION -----

First a note about High Sierra and ISO 9660 CD-ROM formats. High Sierra was established first. Initially, the format was presented in a working document. Several CD-ROMs were published from this "not quite" final document. These CD-ROMs may not be readable by all "High Sierra" drivers.

Next, International Standards Organization (ISO) used the High Sierra document as the basis for their standard ISO 9660 CD-ROM format. Most developers of CD-ROMs for multiple platform products now use the ISO 9660 standard. The ISO 9660 format is supported by the Apple II and Macintosh CD drivers and by MS-DOS Extensions Version 2.0 and up. As a result, you may want to use the ISO 9660 standard.

For a High Sierra/ISO 9660-type format, a decision must be made about what will be placed on the disc. This is especially important when the information will be used on a variety of different computer systems. The files that will be placed on the CD-ROM should be readable by all types of computers that are expected to read the data. The ASCII text file is one type of file that is universal to most computer systems.

Applications may not be the best thing to place on a disc that will be used in different computers. Generally, an application that runs on one type of computer will not run on another type. However, Meridian Data, Inc. has a CD-ROM which contains both Macintosh and MS-DOS applications in a ISO 9660 format while maintaining Macintosh file integrity. They have apparently worked out a method to accomplish this hybrid disc.

If the information will be read by a search and display application of the developer's design, then the type of file to be used can be designed to function as needed by the developers. This will require the developer to write individual search and display applications for each of the different computers using the CD-ROM.

Different mastering/pressing facilities request differing formats for the source materials. For ISO 9660, some facilities require that the source material be in ANSI files on a 1/2-inch, 9-track tape with 6250 bytes per inch, while others will accept ANSI image, ANSI files, IBM image, unlabeled image formats on a .5-inch, 9-track tape. Other formats and media include TK70 image or TK70 files on cartridge tape or on an AFA WORM formatted optical disc. Thus, to determine what format the data needs to be in, contact your mastering facility to find out what format they want for the source material.

Once the CD-ROM developer has agreed with the mastering/pressing facility on the format and medium, the source material is sent to the facility. Often a test pressing is provided for the developer to verify that all is correct with the transfer from source material to CD-ROM. On approval of the test pressing, the facility then presses the requested number of CD-ROM discs.

To determine when a CD-ROM pressing becomes feasible, compare the cost of alternate methods of distribution to the cost of CD-ROM distribution. People often consider the breakeven point to be 100 copies at 10-20MB per copy.

A more sophisticated method involves the use of the premastering facility. A premastering facility provides an intermediary service between the developer and the mastering/pressing plant. The service can consult with you about creating a successfully-designed CD-ROM and properly format all data destined for the CD-ROM.

Mastering and pressing facilities include 3M Optical Recording Department, Discovery Systems, and Digital Audio Disc Corporation. For premastering, contact Optical Media International and Meridian Data. For more details, search the Technical Info library under the appropriate company name.

## A/UX: Optimizing X Window Performance (9/94)

Revised: 9/22/94  
Security: Everyone

A/UX: Optimizing X Window Performance (9/94)

Article Created: 28 December 1989  
Article Reviewed/Updated: 22 September 1994

TOPIC -----

I am working on a port of an HP X Window System application, using a Macintosh IIci with 8MB of internal memory. The issue is X-Window display performance.

The display of the X Window System application is faster when the X-server part is used over the network on an HP Model 340, than when the X-display is used on the Macintosh IIci itself!

The kernel has been modified with kconfig as is described in the "X Windows System User's Guide," page 2-6.

Can I get additional optimization by modifying other parameters or in future versions of Apple's X Windows product.

DISCUSSION -----

This is normal behavior for an X environment. Overall performance depends on the combined performance of the host running the X server and the host running the X clients. Network speed is also important, but assuming Ethernet speeds, not so much as computing performance. If both the client and server are running on the same computer, then the combined load will predictably degrade performance.

Because your customer is running the server on the Macintosh IIci, you should make sure they understand the implications of using NuBus versus built-in video with anything other than 1-bit displays. Using built-in video in 8-bit mode could severely impact performance.

Optimizing an X system is similar to optimizing any A/UX networking system. You can improve performance by optimizing the following:

- Available RAM. Install 5MB or more, 8MB if running both server and

clients. In A/UX 3.0, at least 8MB of RAM is recommended.

- Kernel parameters like NBUF and NMBUFS. At least 600 block I/O buffers (NBUF) and 200 network buffers (NMBUFS) is recommended.
- Speed and location of swap space. This can be faster if swap space is located on a second drive.

## Quantum Disk Drives: Lubricant Effects on Head Seeks

Revised: 3/4/90  
Security: Everyone

Quantum Disk Drives: Lubricant Effects on Head Seeks

=====

This article last reviewed: 4 January 1990

TOPIC -----

I know that the new Quantum ROMs do occasional seeks to overcome the lubricant problem on their hard disks. I thought that these seeks would take only a few seconds, but we're getting reports that the seeks go on for five minutes, usually just after a save. Is this correct?

DISCUSSION -----

It's possible for this to happen, especially if the save resulted in a number of writes in a very small area. This would result in puddles of lubricant forming outside this "save" area. When the head tries to move elsewhere, it encounters the puddle and loops through a move sequence until it breaks through the puddle. Your customers should not be overly concerned, because it's not a major problem, but the Quality group is looking into the issue.

## HyperCard: XCMD To Restart & Shutdown Macintosh

Revised: 6/10/91  
Security: Everyone

HyperCard: XCMD To Restart & Shutdown Macintosh

=====

Article Created: 4 March 1990  
Article Last Reviewed: 29 March 1991  
Article Last Updated: 29 March 1991

TOPIC -----

Do you know of a HyperCard XCMD that can restart the Macintosh?

DISCUSSION -----

There are several XCMDs and XFCNs capable of restarting or shutting down a Macintosh. One, named "doRestart," restarts the Macintosh without any further notice. The other, named "ShutDown," does a normal shutdown as if you had selected Shut Down from the Finder's Special menu. The "Shutdown" XCMD eventually corrupts any stack it's used in. It's just a matter of time before the user shuts the system down without HyperCard having done its housekeeping chores. The shareware "SafeShutDown" by Christopher Watson seems to be safe (there have been no reports of corrupted stacks with it). None of these is an Apple-supported solution.

Caution should be used when executing these, especially while MultiFinder is running. It is possible that other applications may not be able to clean up properly before the system restarts or shuts down.

An easier, faster and safer way to do this is to create a QuickKey sequence for HyperCard to execute.

The HyperTalk script might look like:

```
on doMenu which
  if which = "Quit" then
    type "Q" with Command key and Option key
  ...
  ...
```

where Command Option Q calls a quickKey sequence that quits HyperCard and then does a Finder shutdown.

Macintosh IIci: Internal Video Circuitry Versus Video Card

=====

Article Created: 4 January 1990  
Article Last Reviewed: 7 July 1992  
Article Last Updated:

TOPIC -----

North American Philips Electronics makes a color RGB monitor that works well (with appropriate cable) with the Macintosh 8-Bit Color Video Card. However, when attached to the Macintosh IIci built-in video port, the monitor displays a blank screen.

They have tested their monitor with the Macintosh IIci in combination with the 8-Bit Video Card, and it works OK. Can you provide a specific list of differences (pinouts, voltages, signal characteristics) between the RBV port and the 8-bit card port?

DISCUSSION -----

The most likely cause of the problem is that the cable or monitor being used does not ground pin 4. This is required for the built-in video circuitry to identify a monitor as an AppleColor High-Resolution RGB Monitor or equivalent. If none of the Monitor ID pins are grounded, the built-in video assumes no monitor is attached.

The following portion of text from the Macintosh IIci Technical Tour stack should clarify why the internal video circuitry of the Macintosh IIci behaves differently than the Macintosh II High-Resolution Video Card. Here is the text:

The Macintosh IIci has the equivalent of a video card built into the main logic board. This means that Macintosh IIci owners do not have to purchase a separate video card to use an Apple monitor with the unit. This also means that all three NuBus slots remain available for other NuBus cards. Other video cards can be added to any one of the three NuBus slots.

The built-in video circuitry supports the following monitors:

Apple High-Resolution Monochrome (@ 2, 4, 16, and 256 colors/grays)  
AppleColor High-Resolution RGB (@ 2, 4, 16, and 256 colors/grays)  
Apple Macintosh Portrait Display (@ 2, 4, and 16 colors/grays)

The pinouts for this port are as follows:

|       |             |                      |
|-------|-------------|----------------------|
| 01    | RED.GND     | Red Video Ground     |
| 02    | RED.VID     | Red Video            |
| 03    | CSYNC       | Composite Sync.      |
| 04    | MON.ID1     | Monitor ID, Bit 1    |
| 05    | GRN.VID     | Green Video          |
| 06    | GRN.GND     | Green Video Ground   |
| 07    | MON.ID2     | Monitor ID, Bit 2    |
| 08    | nc          | (No Connection)      |
| 09    | BLU.VID     | Blue Video           |
| 10    | MON.ID3     | Monitor ID, Bit 3    |
| 11    | C&VSYNC.GND | CSYNC & VSYNC Ground |
| 12    | VSYNC       | Vertical Sync.       |
| 13    | BLU.GND     | Blue Ground          |
| 14    | HSYNC.GND   | HSYNC Ground         |
| 15    | HSYNC       | Horizontal Sync.     |
| Shell | CHASSIS.GND | Chassis Ground       |

The pin requirements for making a cable for a Macintosh IIfx to a Portrait display are as follows:

| DB-15 (Macintosh IIfx) | DB-25 (Portrait) |
|------------------------|------------------|
| 03                     | 05               |
| 07                     | 08               |
| 08                     | 04               |
| 10                     | 03               |
| 11                     | 07,10            |
| 12                     | 02               |
| 14                     | 01               |
| 15                     | 06               |
| Shell                  | Shell            |

There is an issue with some third-party video cables and third-party video cable extenders. Some of those cables included just the necessary pins to support the Apple High-Resolution Monochrome Monitor or the AppleColor High-Resolution RGB Monitor with the Macintosh II High-Resolution Video Card.

One problem with some of these cables is that pins 4, 7, and 10 are used to identify the monitor that is connected. With the Macintosh II High-Resolution Video Card, pin 4 was a ground line, but pins 7 and 10 were not used. With the color and monochrome monitors, the problem is that some of those cables leave out pin 4, and tie to another ground. In these cases, the built-in video fails to detect and identify the monitor.

This causes built-in video to be disabled. However, if the cable or cable extender connects pin 4, the cable should allow the Macintosh IIci to correctly identify the Apple High-Resolution Monochrome and the AppleColor High-Resolution RGB Monitors. Most cables support the other signals required for these two monitors.

A second problem is that, given the fact that the new Macintosh IIci-to-Portrait Display cable has a 15-pin connector on one end, it can be connected to third-party video cable extenders. However, all of the lines that were unused by the Macintosh II High-Resolution Video Card are now used to support the Macintosh Portrait Display. As a result, any video cable extender that does not include these lines will not support the Portrait Display. In this case, the Macintosh IIci may not be able to identify the monitor because lines 7 and 10 probably will not be connected and the required video signal lines will not be there either.

SPECIAL NOTE: To meet FCC part 15 requirements, the Apple-supplied cables have to be used.

Macintosh: Korean-Language Word Processors

=====

This article last reviewed: 4 January 1990

TOPIC -----

Do you know of a Korean-language word processor?

DISCUSSION -----

The Apple distributor in Korea, Elex Computer, has developed the HangulTalk 6.0.2 with Apple Far East. It has full Korean-language support and Hangul PostScript printing.

For word processing, Elex Computer has worked with Paragon Concepts to localize the Nisus word processor. The Korean version has full script-manager support plus in-line Hangul input. Besides Nisus, a Korean version of Quark XPress is also available.

Please contact Elex Computer for details. For more details, search the Tech Info Library under "Elex."

## LocalTalk: High-Speed LAN Bridging at Speeds up to 57.6K BPS

Revised: 3/4/90  
Security: Everyone

LocalTalk: High-Speed LAN Bridging at Speeds up to 57.6K BPS

=====

This article last reviewed: 5 January 1990

TOPIC -----

I need a high-speed LAN bridge to link buildings on a business "campus." Can you help me?

DISCUSSION -----

High-speed LAN bridging is possible with the Digital Access A-115 Asynchronous Line Driver and the Shiva TeleBridge. With these products, two LocalTalk LANs as far apart as 3.5 miles can be bridged at speeds up to 57.6K bps. All connections are over twisted-pair copper wiring. Installation is simple, and, because all connections are over existing wiring, there is no high installation cost. For more information, search the Tech Info Library under "Digital Access Corporation".

LocalTalk PC Card: Accessing a Host Running TCP/IP

=====

This article last reviewed: 5 January 1990

TOPIC -----

Is there a product for DOS that can be configured to use the Apple LocalTalk PC Card to open a connection to a host system running TCP/IP?

DISCUSSION -----

Yes. The product is NCSA Telnet for DOS. Like the version for the Macintosh, the DOS version is available from the Supercomputer Research Center at the University of Illinois. Judging from comments on USENET, setting up the required configuration file is not for the faint-hearted.

For more details, search the Tech Info Library under "NCSA Telnet."

## A/UX: Internet Router Printing Problem (8/94)

Revised: 8/23/94  
Security: Everyone

A/UX: Internet Router Printing Problem (8/94)

Article Created: 5 January 1990  
Article Reviewed/Updated: 19 August 1994

TOPIC -----

I have a problem printing from AppleTalk for A/UX (Ethernet) through the AppleTalk Internet Router. I am running A/UX and have three printers--a LaserWriter IINTX and two AppleTalk ImageWriters on LocalTalk.

On the A/UX machine, I can launch a Macintosh OS application and print through Ethernet to the Internet Router and on to the LaserWriter with no problems. The Chooser works fine and shows all zones and printers.

However, when I try to print through A/UX, none of the three printers prints with lp, lpr, or atprint. The Printers and Zones show up and are chosen with the at\_cho\_prn script. Do you have any suggestions?

DISCUSSION -----

Because you don't have a printing problem via a Macintosh OS application, the problem seems to be on the A/UX printer spooler setup.

We have a couple of A/UX machines here configured with AppleTalk for A/UX printing via EtherTalk and the AppleTalk Internet Router without any problem when using the "lp" command or printing directly from the Macintosh OS application.

Here are some questions and suggestions:

- Is the /usr/lib/lpsched running? It usually starts up from the /etc/inittab.
- If the printing interface is via EtherTalk, the following two lines must be included in the /etc/appletalkrc file:

```
interface = ethertalk0
```

Ethernet = ae0

- Did you run the "ADD\_AT servicename" command when you set up the printer spooler? (Note that servicename is just a printer queue name. You can give any name you want.)
- Try the "lpstat -t" command to display the current status information of your printer system. Make sure that the system default destination is the one you want to print to. Are the printer queue and the Class AppleTalk both accepting requests? Is the printer queue enabled?
- Make sure you have the Internet Router set to route the AppleTalk Phase 2 packets.

## A/UX: vt220 termcap

Revised: 9/25/92  
Security: Everyone

A/UX: vt220 termcap

Article Created: 5 January 1990

### Article Change History

-----  
08/31/92 - REVIEWED  
o For technical accuracy.

### TOPIC -----

I am looking for a UNIX platform to transport accounting applications. The main problem to transport is termcap. I need a vt220 entry.

### DISCUSSION -----

Here is a copy of the vt220 termcap entry adopted from a 4.3BSD UNIX machine. We don't have any VT220 terminal to test these entries though.

We've checked this and some contain the same entry as in A/UX 1.1, so you may need to change them to different entry names. Here is the entry:

## AppleTalk: Macintosh ROM Version Numbers (4/93)

Revised: 4/15/93  
Security: Everyone

AppleTalk: Macintosh ROM Version Numbers (4/93)

Article Created: 5 January 1990

### Article Change History

04/06/93 - UPDATED

- To include new computer models, and the effect of System 7.x and AppleTalk version in Macintosh ROM. Article retitled.

### TOPIC -----

What is the version of AppleTalk found in the Macintosh ROMs?

### DISCUSSION -----

The ROM version of AppleTalk is irrelevant today. Starting with System 7, AppleTalk is included with System Software. In most cases, the version of AppleTalk that is included in the version of System 7.x is newer than what is built-in to ROM.

For Macintosh systems that can use System 6, we recommend using the latest Network Software Installer to install AppleTalk software. This is a good idea for System 7.x users as well. This ensures that the customer is using the most up-to-date AppleTalk software with their systems. In almost all cases, this will provide AppleTalk software that is newer than what is available in ROM.

Below is a list of the AppleTalk versions in the ROM of various Macintosh systems:

| System          | ROM AppleTalk Version |
|-----------------|-----------------------|
| -----           | -----                 |
| Macintosh 512Ke | 19                    |
| Macintosh Plus  | 19                    |

|                         |                                                                                                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------|
| Macintosh SE            | 48                                                                                                                    |
| Macintosh II            | 49                                                                                                                    |
| Macintosh IIX           | 49                                                                                                                    |
| Macintosh SE/30         | 49                                                                                                                    |
| Macintosh IICx          | 49                                                                                                                    |
| Macintosh Portable      | 52                                                                                                                    |
| Macintosh IICi          | 52                                                                                                                    |
| Macintosh IISI          | 54                                                                                                                    |
| Macintosh IIfx          | 54                                                                                                                    |
| Macintosh IIVx          | 54                                                                                                                    |
| Macintosh Classic       | 46                                                                                                                    |
| Macintosh Classic II    | 56.0.1                                                                                                                |
| Macintosh Color Classic | 57.0.4                                                                                                                |
| Macintosh LC            | 54                                                                                                                    |

TOPIC -----

What is the maximum number of windows that I can open at once under the Finder and MultiFinder? Can I increase this?

DISCUSSION -----

Finder 6.x allows a maximum of 13 windows open at once. You can use ResEdit to change this value. Here are the steps:

- 1) Work only on a COPY of your Finder.
- 2) Start ResEdit.
- 3) Open the Finder file from ResEdit.
- 4) Open the LAYO resource named ID=128. (It's probably the only one of that type.)
- 5) Scroll until you find the layout default called "Max # of windows". It's at the bottom of the list.
- 6) Change this to the desired value.
- 7) Quit ResEdit and answer Yes to "Save 'Finder' before closing?"

Changing this value to a higher number causes the Finder to use more memory. You may have to allocate more memory for the Finder, if you are running MultiFinder.

## Macintosh to IBM AS/400 Connectivity (7/93)

Revised: 7/19/93  
Security: Everyone

Macintosh to IBM AS/400 Connectivity (7/93)

=====

Article Created: 5 January 1990  
Article Reviewed/Updated: 16 July 1993

TOPIC -----

How do you connect the Macintosh to IBM AS/400s. Are there other ways to connect local Macintoshes to AS/400 without using a KMW box?

DISCUSSION -----

You can to connect Macintosh into the IBM AS/400 with both Apple and third-party products. You may use either Apple's SNA•ps 5250 stand alone product, or SNA•ps 5250 GC with one of the SNA•ps Gateway products. Two third-party companies, IDEAssociates and Andrew Corporation, provide terminal emulators for connecting a Macintosh computer to an IBM AS/400.

The IBM AS/400 uses System 3x architecture. The recommended connection is the 5250 family of devices.

The AS/400 will also support 3270 devices in pass-thru mode to locate mainframes using LU 6.2. This support is for IBM's SAA.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Article Change History:  
07/16/93 - Included SNA•ps 5250 product family.  
02/16/93 - KMW now Andrew Corporation.

Interleaf: How To Display Output on a Macintosh

=====

This article last reviewed: 5 January 1990

TOPIC -----

Can you give me in any tips about displaying Interleaf output files on the Macintosh?

DISCUSSION -----

Some of the challenges inherent in this situation included incompatible versions of the software on the Macintosh and the Interleaf environment. Here is a list of the current Interleaf software offerings.

- Interleaf Publisher - Macintosh II, desktop publishing application combines word processing, drawing and painting, charting and graphing, long document management, page layout, and workgroup publishing tools.
- Technical Publishing Software - Provides PostScript output on the Sun, DEC, Apollo, or IBM RT PC machines.
- IBM Interleaf Publisher - Provides PostScript output for the IBM 386 PC.
- PC ViewStation - IBM PCs and compatibles, WYSIWYG document viewing program that lets users display and annotate Interleaf documents.

This product runs on a PC-XT or compatible. SoftPC, from Insigna Solutions, provides PC-XT emulation. Using SoftPC on the Macintosh, we were able to view the Printerleaf file as output from the Technical Publishing Software. Therefore, the software incompatibility issue became a moot point. Just to recap, using SoftPC running the PCViewstation software, you can view and annotate the Interleaf output files.

TOPIC -----

I would like to make my Macintosh Portable generate color output to a color monitor. Is this possible?

DISCUSSION -----

Aura Systems has a box that plugs into the SCSI port of a Macintosh 512Ke, Macintosh Plus, Macintosh SE, and Macintosh Portable.

ScuzzyGraph II produces high-resolution, color graphics. ScuzzyGraph II can ouytput 16 colors and is QuickDraw-compatible. It gives users screen sizes up to 650 percent larger than the built-in Macintosh SE screen with resolution up to 1,280x1,024 pixels. You can print color on the ImageWriter II or ImageWriter LQ with a color ribbon in place or on an HP PaintJet printer.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

## TokenTalk NB Confidence Test: Incompatible with System 6.0.4

Revised: 5/27/92  
Security: Everyone

TokenTalk NB Confidence Test: Incompatible with System 6.0.4

=====

Article Created: 5 January 1990  
Article Last Reviewed: 22 May 1992  
Article Last Updated:

TOPIC -----

Why can't I run the TokenTalk NB Card User Confidence Test on my Macintosh IIci?

DISCUSSION -----

The TokenTalk NB Card User Confidence Test cannot run on any Macintosh that requires system software version 6.0.4 or later because of a code conflict problem. The Confidence Test ships with version 6.0.3 and was designed to start up as a diagnostic.

If you copy the test to a startup disk or a Macintosh hard drive running version 6.0.4 or later, the system software loads the test code incorrectly into system RAM. The upshot of this is that the test either fails the card or hangs the Macintosh in the process of running the test.

Users should run the test only on a Macintosh that can start up the test disk. There is no other workaround.

## A/UX: NFS Record Delimiters and VAX RMS Formats (9/94)

Revised: 9/7/94  
Security: Everyone

A/UX: NFS Record Delimiters and VAX RMS Formats (9/94)

=====

Article Created: 5 January 1990  
Article Reviewed/Updated: 6 September 1994

### TOPIC -----

My VAX systems use four file formats: LF, CR/LF, Fortran, and Variable Length. However, the VMS systems use LF, and the Ultrix systems use CR/LF. Both must go through a conversion process to use the files across VAX platforms. Which file format does Apple's NFS and Cayman's NFS support to avoid having to support a third file format.

### DISCUSSION -----

NFS on A/UX uses LF, and the Macintosh OS uses CR for record delimiters. The Cayman GatorBox automatically converts files from one format to another.

The items you mentioned are not file formats. Rather, LF and CR/LF are variations of the Stream record format. Variable Length is a record format, and FORTRAN carriage control is a record Carriage-Control attribute. CARRIAGE\_RETURN attribute is the default and specifies that each record is preceded by a line feed and is followed by a carriage return when the record is written to a carriage-control device, like a line printer or a terminal. FORTRAN attribute specifies that the first byte (byte 0) of each record contains a FORTRAN carriage-control character. A space in this byte means single-space, a 0 (zero) means double-space, a 1 means Page Eject, and so on.

Here is a description of the file and record formats supported by VAX RMS. VAX Record Management Services (RMS)--the file and record access subsystem of the VAX/VMS operating system--supports three file organizations. These are sequential, relative, and indexed. It also supports four record formats:

- Fixed length: all records in a file are the same length.
- Variable length: each record is only as long as the data within it requires.
- Variable length with fixed-length record (VFC): similar to

variable-length records except that a fixed-length control field is prefixed to the variable-length data portion.

- Stream: records are delimited by special characters or character sequences called terminators, which are part of the record they delimit.

Within the Stream record format, there are three variations:

- STREAM\_CR: each record is terminated using a carriage return character.
- STREAM\_LF: each record is terminated using a line feed character.
- STREAM: you have the option of specifying the terminating character from a limited set of special characters, including the carriage return character (CR), the carriage return/line feed character (CR/LF) pair, the form feed (FF) character, or the escape (ESC) character.

A/UX: Available Third-Party Optical Drives

=====

Article Created: 8 January 1990  
Article Last Reviewed: 27 September 1991  
Article Last Updated: 27 September 1991

TOPIC -----

Can you give me a list of optical drives for A/UX?

DISCUSSION -----

This article includes information on tape drives from:

- Conversion Dynamics, Inc
- Macsetra Technologies International, Inc. (Canada)
- Peripheral Land, Inc.
- Racet Computers, Ltd.
- Ricoh Corp. (Peripheral Products Division)
- Software Architects, Inc.
- Storage Dimensions
- Summus Computer Systems
- Sumo Systems

All the listings below were valid as of December, 1989. For further manufacturer information, search the Tech Info Library under the manufacturer's name.

Conversion Dynamics, Inc.  
-----

Conversion Dynamics's Optirase is an external SCSI, 5.25-inch, erasable optical-disk subsystem. It has a total capacity of 600MB for storage and provides a convenient way to back up or offload data from any mountable volume and distributes the information from one system to another.

Macsetra Technologies International, Inc. (Canada)  
-----

Macsetra's Genesis 6000 is a rewritable 600MB optical drive using fully-removable 5.25-inch cartridges. It is a fully bootable device and makes use of Macintosh icons, system utilities, backup routines, and ejectability. Its own proprietary software includes automatic bad-block management and sophisticated memory caching to increase all-around speed and performance.

Peripheral Land, Inc.

Peripheral Land's Infinity Optical is a fully rewritable, magneto-optical drive that has a formatted capacity of 573MB. It features sustained data transfer rates of 7.4 megabits per second and an average access time of 75ms. It has the option of 512K or 1024K sectors. The double-sided, 5.25-inch cartridges can be formatted to be compatible with Macintosh OS, MS-DOS 3.0, or A/UX. It comes bundled with backup software, laser printer spooler, RAM-based disk drive accelerator, disk optimizer, defragmentation software, and security software.

Racet Computers, Ltd.

Racet's Stand-Alone Series Cosmos 600 is a magneto-optical erasable drive and has a formatted capacity of just under 300MB per side on two-sided media. It provides regular archive backups and has full-featured, system-level software. Access times are 70ms average, with a burst transfer rate from 128K on-board cache of 1.2MB per second.

Ricoh Corp. (Peripheral Products Division)

Ricoh's RO-5030E is a rewritable, optical drive that provides speedy data access in only 71ms. It offers 594MB of fully rewritable storage on a removable, two-sided, magneto-optical disk. The transfer rate at the unit's SCSI interface is up to 1.4MB per second. Its mean time between failures is rated at more than 20,000 hours of operation.

Software Architects, Inc.

Software Architects, Inc. have an optical disk drive (both Sony and Ricoh) product called Formatter II for A/UX. It is a read/write magneto-optical disk drive with a capacity of about 610MB (about 300MB on each side). This product comes with the driver, utility, and scripts for A/UX. The utility lets you initialize and partition very much as the Macintosh HD Setup program does. The shell scripts allow manipulating the operation of optical disk in A/UX (for example, ejecting the cartridge).

Storage Dimensions

Storage Dimensions's LaserStor Erasable is an erasable optical disk drive, featuring a SCSI interface and one 1GB (1,000MB) erasable media cartridge. ANSI standard cartridges are also available in capacities of 650MB. MacinStor Installer software, featuring device driver, partitioning, password-protected partitioning, drive diagnostics, and automatic reallocation of bad blocks, is included. It provides an average seek time of 35ms and data transfer rates of 10Mbps.

Summus Computer Systems

-----  
LightDisk-512 is a rewritable, magneto-optical disk drive with a capacity of 600MB per optical disk. It provides the convenience of removable media with performance approaching that of fixed drives (an average seek time of 90ms with a data transfer rate of 680Kbps).

Sumo Systems

-----  
RSSM600 is a rewritable optical disk subsystem that includes a 600MB optical disk in an enclosure with power supply, SCSI cable, and INIT-installation software package. It has a fast access time of 50ms and can be used as the boot device. The software has advanced features, like automatic on-line formatting, automatic defect management, automatic cartridge change control, and intelligent SCSI interface providing a high data-transfer rate.

## A/UX: Available Debugging Tools (9/94)

Revised: 9/21/94  
Security: Everyone

A/UX: Available Debugging Tools (9/94)

Article Created: 4 March 1990  
Article Reviewed/Updated: 21 September 1994

TOPIC -----

What tools are available under A/UX for debugging Macintosh OS applications, particularly, Macintosh OS applications developed using MPW?

DISCUSSION -----

The "sdb" and "adb" are two debugging tools currently available and supported by A/UX.

However, using "sdb" or "adb" to debug Macintosh applications on the console creates a problem; that is, once it is started, all input is grabbed by the toolbox interface, making it impossible to use the keyboard to communicate with "sdb" or "adb". A workaround to this was posted previously, and has been incorporated here for your convenience:

"There is a simple way to debug toolbox applications under A/UX. Log on from another terminal (connected over a serial line or network; that is, via 'telnet' or 'rlogin'), and start up the toolbox application with 'sdb'. The toolbox ALWAYS takes over the console (keyboard, screen, and mouse), so when started from 'sdb', it will run as expected. When you give an interrupt from the terminal you logged on with or for some other reason to get back, 'sdb' will be responding on the terminal you logged on with again.

"This is, in fact, a very useful feature: the console screen will not be disturbed by the debugging output."

You can get a third-party debugger called "CDB" for A/UX from Third Eye Software. This program was also available from APDA (Apple Programmers and Developers Association), but may not be any longer. It is an extremely powerful source-level debugger. Features include breakpoint, assertions, formatted structure dumps, full signal handling, command record and playback, alternate source directories, initialization files, statement- and instruction-level

single-stepping, and more. For more information on "CDB" please contact Third Eye Software.

## Token Ring: Macintosh SE Card Available in Scandanavia

Revised: 7/27/93  
Security: Everyone

Token Ring: Macintosh SE Card Available in Scandanavia

=====

Article Created: 4 March 1990  
Article Reviewed/Updated: 27 July 1993

TOPIC -----

Is anyone marketing a Token Ring board for the Macintosh SE in Scandanavia?

DISCUSSION -----

EuroComm, Inc. has the international marketing rights for MacRing SE from Asante Technologies, Inc. (formerly h-three) in North Carolina and uses Nova International as the Scandinavian distributor. MacRing SE is used for:

### 1) Macintosh SE to Macintosh over a Token Ring link

Shipped with each board is a completely TokenTalk-compatible driver allowing full access to AppleTalk over a Token Ring link at 4Mbps. Thus, any software designed to run over AppleTalk can be used, and the Token Ring link becomes transparent. It has been tested with Microsoft Mail, Word, Excel, TOPS 2.1, and Timbuktu.

### 2) IBM PC Access to AppleShare File Server

An IBM PC can access a Macintosh set up as an AppleShare File Server with AppleShare PC 2.0.

### 3) Macintosh Access to IBM File Servers

Miramar Systems' MacLAN lets the MacRing SE user access any IBM file server, like Novell, PCLAN, and 3COM.

### 4) 3270 support so that a MacRing SE user can access IBM mainframes using the same Token Ring-to-mainframe connections as PCs (for example, IBM 3174, IBM 37X5 T1C, and other Token Ring gateways).

To locate a vendor's address and phone numbers, use the vendor name as a search string.

## A/UX: U.S. and International Encryption Differences (9/94)

Revised: 9/20/94  
Security: Everyone

A/UX: U.S. and International Encryption Differences (9/94)

=====

Article Created: 4 March 1990  
Article Reviewed/Updated: 20 September 1994

### TOPIC -----

The international version of A/UX contains only password encryption, while the U.S. version contains file encryption. Is this the only difference between them?

How does the file encryption works? Is there any command to encrypt the file or environmental setting for file encryption?

### DISCUSSION -----

Yes, the only difference between the U.S. and international versions of A/UX is the inclusion of encryption software. The U.S. version of A/UX includes file encryption software that is not included in the international version. This software is based on the National Institute of Standards and Technology DES (Data Encryption Standard) algorithm, and cannot be exported outside of the United States and Canada. The encryption software includes "crypt" and new versions of ed, ex, and vi.

There are no special environmental settings used by "crypt." It reads standard input and writes to standard output. It lets you enter the key on the command line, and prompts for one if none is supplied. Unencrypting works in much the same way, with "crypt" prompting for the key if none is supplied.

## Macintosh Display Cards Overview (2 of 3)

Revised: 7/16/90  
Security: Everyone

Macintosh Display Cards Overview (2 of 3)

=====

This article last reviewed: 19 March 1990

(This is a continuation of, "Macintosh Display Cards Overview (1 of 3)")

### - Convolution

The 8/24 Macintosh video cards address interlaced display flicker by running every pixel through a formula that averages the pixel with its individual neighboring pixels above and below. This technique is called convolution and it is part of the function of the CLUT/DAC chip. Convolution causes an averaging effect between scan lines so that a horizontal line includes at least a portion of the scan lines above and below its own scan line. A portion of the horizontal line remains visible during display of both the odd and even fields to avoid flicker. The convolution formula follows a 1:2:1 ratio where the current pixel value is given twice the weight of its neighbors above and below.

The 4/8 does not support convolution; the 8/24 supports convolution at up to 8-bits per pixel automatically turning it on where appropriate. If a Display Card 8/24 is driving an interlace display in 24-bit mode, convolution is disabled. If the card is driving an interlace display in 8-bit, or a lesser pixel depth, convolution is enabled.

### - Underscan and Overscan

The full 640 x 480 active video display is visible on an interlaced monitor if the monitor operates in underscan mode. (Underscan means that the monitor screen is larger than the active video display.)

Many monitors do not show the full active video display area much because the picture extends beyond the edges of the screen. This mode is called overscan because the scanned image is larger than the display area. (Television sets use overscan.)

To guarantee that the whole image is visible on an overscan monitor, all three

new display cards can be switched to overscan mode, which produces a smaller display with only 512 x 384 pixels.

The new display cards can support both overscan and underscan monitors.

- Memory Organization

The frame buffer controller is a custom gate array that serves as the controller for the 4/8 and 8/24 display cards. The frame buffer implements an address translation scheme that allows the cards to use only 1MB to support 24-bit graphics even though a 640 x 480 monitor displaying 24-bit graphics would normally require 1.2MB of VRAM. The 8 bits of data in each pixel that do not convey any color (or gray-scale) information are ignored. Such compaction allows 24-bit data for a 640 x 480 monitor to fit in just over 900K of VRAM. The eight bits that are ignored are defined as the alpha channel and, when maintained, can be used for special effects.

#### Macintosh Display Card 8/24 GC

The Macintosh Display Card 8/24 GC has the entire feature set of the Display Card 8/24, with rapid drawing of 24-bit images. Display Card 8/24 GC is a stand-alone display card that extends the 8/24 to include dramatic performance acceleration. Unaccelerated 24-bit imaging can be slow, but Macintosh Display Card 8/24 GC uses several methods to provide a thorough and integrated solution. Macintosh Display Card 8/24 GC accelerates the drawing of images by 5 to 30 times, with greatest acceleration when drawing very complex images. (Users of applications that circumvent QuickDraw will see very little acceleration.)

The 8/24 GC supports convolution for interlaced displays at up to 8 bits per pixel. 8/24 GC resident video RAM is not compressed the way it is on the 4/8 and 8/24 cards, which means the the extra alpha channel byte is maintained.

- Accelerating Graphics

One effective method for accelerating graphic imaging is the use of a co-processor dedicated to drawing images. This frees the 680x0 to continue program execution without having to wait for the time-consuming imaging of 8 to 24-bit pixel images. The Macintosh Display Card 8/24 GC card uses the Am29000 RISC-based microprocessor to relieve the 680x0 of the imaging process. The AM29000 was chosen instead of a graphics processor because specialized graphics processors are inadequate for Display Card 8/24 GC; they are unable to handle complex QuickDraw operations and setup code.

- Inter-Process Communication

Display Card 8/24 GC uses a unique Inter-Process Communication (IPC), streamlined for low overhead and fast response time. The Display Card 8/24 GC resident IPC intercepts QuickDraw calls on the Macintosh and passes them and their parameters to the special version of 32-bit QuickDraw that resides on Macintosh Display Card 8/24 GC. The IPC also makes it possible for the customized Macintosh Display Card 8/24 GC QuickDraw to call specific routines running on the Macintosh.

- NuBus Data Transfer

Transferring large and deep bitmaps across the NuBus is the slowest part of the drawing process. Typical reads and writes, from the Macintosh to the display cards, are performed in 1000 and 500 nanoseconds respectively. NuBus data transfer time is affected by the need to re-arbitrate for control of the bus after each 32-bit word is transferred.

The Display Card 8/24 GC optimizes NuBus data transfer by reading only QuickDraw variables and small portions of data structures across NuBus. The bit maps are then created locally in the Macintosh Display Card 8/24 GC's VRAM. The Display Card 8/24 GC reads and writes to its frame buffer memory at a rate of 66 to 132 nanoseconds, and up to 2MB of DRAM on the card holds offscreen bitmaps.

- 32-bit QuickDraw Optimized For the Am29000

The Display Card 8/24 GC 32-bit QuickDraw produces the same graphic output as standard 32-bit QuickDraw. However, several algorithms have been modified, and internal organization has been altered to fit into the graphics accelerator architecture.

Macintosh Display Card 8/24 GC provides transparent acceleration of any Macintosh application. No extra work need be done by an application to take advantage of Macintosh Display Card 8/24 GC optimized 32-bit QuickDraw.

## A/UX 2.0: Overview

Revised: 1/6/93  
Security: Everyone

A/UX 2.0: Overview

Article Created: 16 July 1990

### Article Change History

-----  
01/05/93 - REVIEWED  
• For technical accuracy.

### TOPIC -----

This article gives an overview of the A/UX 2.0. This overview includes

- New features
- New Hardware Support
- Software Enhancements
- Connectivity Enhancements
- Programming Features
- Standards

### DISCUSSION -----

#### A/UX 2.0 New Features

-----  
The Apple A/UX operating system Version 2.0 provides access to the Macintosh desktop within the UNIX environment. Users can run multiple Macintosh productivity applications, UNIX applications, and X Window System applications simultaneously.

The Macintosh Finder is hosted by A/UX Version 2.0 and is the default user environment. From the Finder a user can launch Macintosh binary files, UNIX Toolbox applications, "vanilla" UNIX applications in terminal windows, and X Window System applications. Both A/UX and Macintosh file systems appear on the desktop with point and click access to all available files (eliminating the need for the HFX utility).

A/UX Version 2.0 supports multiple, concurrent, Macintosh-Toolbox applications, in addition to concurrent UNIX and X applications in the Macintosh desktop environment. A/UX 2.0 implements the Macintosh Layer Manager and the MultiFinder interface.

Menu-driven commands provide easy startup, login, logout, and shutdown. The user no longer needs to know the technical details of the environment.

Macintosh applications that adhere to the specifications for the Macintosh 32-bit environment (referred to as "32-bit clean") run in the A/UX environment without change. A/UX 2.0 also supports Macintosh applications that are not yet 32-bit clean. At login, you specify creation of a 24-bit, 32-bit, or console emulator environment. To switch between environments, you log out and then log back in without restarting.

The A/UX Version 2.0 Commando interface for all UNIX commands provides dialog-based interfaces for all UNIX utilities that have command-line arguments. You have the choice of typing command line arguments in the conventional way, or running Commando.

UNIX shell windows are now accessible from the Apple menu on the desktop, and a Macintosh, mouse-driven editor eliminates the need to learn a text editor like vi. (The standard editing and processing utilities, including vi, ex, ed, ditroff, nroff, tbl, eqn, and pic are available as alternatives.)

A/UX Version 2.0 supports Callbacks, simulating Macintosh asynchronous I/O by associating a completion routine with a toolbox asynchronous I/O request. When the I/O request is completed, control dispatches to the established completion routine.

The Macintosh Sound Manager provides continuous sampled sound plus note and wavetable synthesizing with calls for both synchronous and asynchronous operations (with callbacks). The A/UX Sound Manager is compatible in all ways with its System 6.0.x counterpart. One notable difference, a result of A/UX virtual memory, is that the A/UX Sound Manager can play sound resources that are larger than physical memory. However, A/UX doesn't implement the MIDI interfaces.

A/UX 2.0 also supports Macintosh applications that require access to the toolbox slot manager and the serial driver providing support for direct-connect printer/plotter devices accessed by toolbox (non-UNIX) calls and for applications like AppleLink and MacTerminal.

A/UX Version 2.0 implements Gestalt (replacing SysEnvirons), providing a cleaner, more efficient method for applications to request information about the current hardware and software operating environment. Gestalt provides the ability to determine information about a large number of system dependent features, like these:

- Type of machine the application is running on
- Version of the System file, AppleTalk driver, and QuickDraw currently running
- Type of CPU, MMU, FPU, and keyboard

- Amount of available RAM, VM, and size of logical pages
- Whether A/UX is running or not

#### New Hardware Support

-----  
A/UX Version 2.0 runs on all Macintosh II systems and on the Macintosh SE/30. Macintosh IIfx support includes the new SCSI DMA, Floppy/ADB PIC (Peripheral Interface Controller) chip, and the SCC PIC chip.

Version 2.0 supports HFS-, A/UX-, and DOS-formatted floppies with capacities of 400K, 720K, 800K, and 1.44M capacities. The AppleCD SC drive can be used as a read-only UNIX file system of up to 500 megabytes, giving information systems providers an inexpensive distribution medium.

#### Software Enhancements

-----  
A/UX Version 2.0 includes the following software enhancements:

- There is now only one Eschatology partition. A new default partitioning scheme accommodates MultiFinder. Version 2.0.1 of HD setup software includes an option to partition a 160-megabyte hard disk.
- The newunix and autoconfig scripts have been augmented by a new script, newconfig. Newconfig uses the same command line arguments as newunix. As an example, to configure a new kernel with NFS and sound, you enter "newconfig nfs snd".
- Processes using the same library routines can share a single copy of the library's object code.
- The user address space, virtual memory maps, and page table management have all been enhanced.
- Accomodation of 32-bit clean ROMs results in smaller patch files.
- The data encryption code is included in the A/UX file system.
- The SASH has been made more Macintosh-like; UFS, System VFS, and A/UX floppies are now accessible through the SASH.

#### Connectivity Enhancements

-----  
A/UX Version 2.0 provides the following enhancements to connectivity:

- A/UX 2.0 supports both X11 (Versions X11R3 and X11R4) and MacX (Version X11R3). (These products are bundled together and sold separately from A/UX 2.0.)
- AppleTalk 2.0 for A/UX is rolled into the 2.0 release.
- A/UX 2.0 supports the MacTCP programmer interface.

- A/UX 2.0 offers access to AppleShare volumes from the Finder Desktop.

#### Programming Features

-----

A/UX 2.0 offers an assembler, a C Compiler, debuggers, the Source Code Control System (SCCS), and related tools to assist in developing new applications or porting existing software to A/UX. Version 2.0 also includes a set of UNIX libraries that let C programs access the functionality of the Macintosh Toolbox. A/UX applications can thus present the Macintosh graphics-based user interface and the traditional UNIX appearance.

#### Standards

-----

The A/UX operating system is source-licensed from AT&T and meets System V Interface Definition (SVID) specifications. Extensions from Berkeley Software Distribution (BSD) Release 4.3 are included in A/UX 2.0, and the release is the IEEE POSIX 1003.1 1988 Full-Use Standard (FUS) and ISO 9945-1.

## Macintosh IIfx: Burst-Mode Access and Page Mode Writes

Revised: 7/14/92  
Security: Everyone

Macintosh IIfx: Burst-Mode Access and Page Mode Writes

=====

Article Created: 14 June 1990  
Article Last Reviewed: 13 July 1992  
Article Last Updated:

TOPIC -----

This articles describes burst-mode memory access and Page Mode Writes as implemented on the Macintosh IIfx.

DISCUSSION -----

### Burst-mode Memory Access

-----

The Macintosh IIfx, like the Macintosh IIfx, supports burst-mode memory access. However, the Macintosh IIfx support burst access for reads and Page Mode Writes, while the IIfx only supported burst reads. The FMC gives the Macintosh IIfx the ability to support burst-mode access. This enables the CPU to read and write groups of data in fewer clock cycles.

On the Macintosh IIfx, burst-mode reads are only done when the data is not located in the internal 256 byte and 32K Static RAM Cache. When the Macintosh IIfx reads from memory, the first access takes 6 clock cycles. The next 3 reads are performed at 3 clock cycles each. This is referred to as "6 3 3 3 burst reads."

Burst-mode access must be supported by the RAM as well as the memory controller. When memory is accessed, we use RAS (Row Address Selection) before CAS (Column Address Selection) to address the chip. We select the row of data we wish to access with a RAS, then assert the CAS lines to select the correct data column. It takes about 3 clock cycles for the chip to select RAS and 3 more cycles to address CAS before the data is ready to read or write.

When burst-mode is enabled, the RAS lines are held high until the burst cycle is over. The memory controller only has to change the column

address (CAS) line to access the next bit of data in that row. It continues to change the CAS line until the burst cycle is over. Because the system does not have to readdress the RAS line, 3 cycles each read/write, it saves 9 clock cycles.

#### Page Mode Write

-----  
A Page Mode Write is similar to a burst-mode read. When data is written out, the system uses Latch Writes for the first write. If the instruction is also a write and the address is within the same page of memory as the previous write, Page Mode Write is used. Page Mode Writes keep the RAS line held high in the save "page" of memory.

## Macintosh Display Cards Overview (1 of 3)

Revised: 7/16/90  
Security: Everyone

Macintosh Display Cards Overview (1 of 3)

=====

This article last reviewed: 19 March 1990

The Apple Macintosh Display Cards 4/8, 8/24, and 8/24 GC greatly extend the performance and flexibility of the Macintosh video card product line. The Display Card 4/8 and the Display Card 8/24 provide the Macintosh II family with a single interface to all Apple displays, and a broad range of graphics capabilities. The Display Card 8/24 GC augments the features of the Display Card 8/24 with the power of a dedicated graphics coprocessor to provide sophisticated graphics capabilities at significantly faster drawing speeds.

The Macintosh Display Card 4/8 provides support for up to 256 colors or grays on the Apple High-Resolution Monochrome and AppleColor High-Resolution RGB Monitors. It also provides up to 16 grays on the Apple Macintosh Portrait Display and Apple Two-Page Monochrome Monitor.

The Macintosh Display Card 8/24 and 8/24 GC support all Apple displays to the maximum of their capabilities, including full 256-level "true grayscale" on all Apple displays. The cards also support full 24-bit "true color" capability on the AppleColor High-Resolution RGB Monitor, which allows users to display any of 16.7 million colors simultaneously. The combination of true grayscale and true color capabilities let you display and work with photographic quality images as well as lifelike simulations, animations, and visual effects.

The Macintosh Display Card 8/24 GC contains an Am29000 RISC-based microprocessor that runs a version of QuickDraw that has been optimized for a coprocessing environment. The Am29000 and the Macintosh CPU work together to speed the QuickDraw environment from five to 30 times depending on the application. As a result, graphics-intensive applications work faster and more smoothly, especially when using full 24-bit color.

All three cards support RS-170 standard timing for compatibility with numerous interlaced video devices. The Macintosh Display Card 8/24 and 8/24 GC provide highest possible quality interlaced video through the use of Apple Convolution.

Macintosh Display Cards 4/8 and 8/24

Macintosh Display Cards 4/8 and 8/24 offer 24-bit color at an affordable price. The following paragraphs discuss the advantages of 24-bit color and features of the 4/8 and 8/24 display cards.

- CLUT and 8-bit Color Images

With the earlier 8-bit Macintosh II video card, each pixel is represented by an 8-bit color value. The 8-bit value is used as an index into a "color look up table" (CLUT), where a 24-bit value is derived from the table of 256 pre-selected colors. The 24-bit value represents the nearest color to the one indicated by the 8-bit pixel value. The 24-bit color value consists of 8-bit values for red, green, and blue; each is then sent through one of the three 8-bit digital to analog converters (DACs) for conversion to analog color signals.

An 8-bit image is drawn by taking each 24-bit pixel value and, using the Color Manager, finding the closest approximation of that color within the CLUT. The 8-bit index of the closest approximate color is then placed in the frame buffer and represents that pixel's value.

Graphic imaging with 8-bit color video is reasonably accurate if the CLUT is set up with colors that are appropriate for the color mix of the image being drawn, and if the image does not require a large number of colors. Very complex colored images tend to lose much of their detail and shading because they tend to be drawn with a high ratio of "best approximation" colors. A color printed copy of a complex color image scanned at 8-bit per pixel could look quite different from the original.

One drawback of 8-bit color is an effect known as "blocking," which refers to the result of several slight variations of a single color being CLUT represented by the same color. This effect makes it difficult to represent subtle shading and leads to a loss of detail. For instance, a very gradual lightening of the color red across an image may be completely represented by single red.

A similarly problematic side-effect of 8-bit color is known as "banding." Banding can be seen in an 8-bit representation of an image made of only a few different colors, but an almost infinite number of shades of those colors. A 256 color CLUT doesn't have enough colors to handle such an image, and it loses subtlety. Areas where one color gradually blends into the other eventually look like bands of one color blending into bands of the other, with each band of color being the CLUT's closest approximation of several marginally different colors.

Dithering is an effect that may allow a closer approximation to the original image. Dithered colors rely upon grouping a number of pixels in a certain pattern to give the effect of a color not found in the CLUT. Since pixels are so small and so close together, a grouping of blue and yellow pixels gives a similar effect to seeing green pixels. While dithering can improve the rendering of a complex image, the result is still an approximation.

- 24-bit Direct Color

24-bit color, also known as Direct Color, avoids the color approximation issues of 8-bit color by allowing 8 bits for each color. 24-bit color delivers an impressive 16,777,216 red green and blue combinations all the color shades discernable by the human eye.

With 24-bit color, color approximation and the CLUT are no longer necessary. 24-bit color is directly interpreted by the video card firmware as each 8-bit red, green, and blue color definition is fed to the appropriate digital to analog converter for output to the monitor. Images that are problematic for 8-bit color video cards can be drawn with all their brilliant nuances by Direct Color. The Display Card 8/24 supports 24-bit color on the Macintosh RGB 13" monitor.

- True Grays

The 256 shades of gray are accomplished by using 8-bits each of red, green, and blue of equal saturation. The 4/8 card supports true grays on all but the Portrait and Two-Page displays, where 16 grays are supported. The 8/24 card supports true grays on the Portrait and Two-Page displays. When driving the two larger monochrome displays, the 8/24 cards use only the blue signal in all its 256 saturation levels to accomplish the full gray spectrum.

- Monitor Support

A programmable pixel clock chip and a 100 MHz oscillator on the new display cards makes it possible to support all current Macintosh monitors. The pixel depth supportable on each monitor is a function of the amount of VRAM installed on the display card. Display Card 4/8 has 512K of VRAM and Display Card 8/24 has 1 megabyte. The 100 MHz oscillator provides support for the Macintosh Two-Page Display.

## Macintosh IIfx: Latched Writes

Revised: 7/14/92  
Security: Everyone

Macintosh IIfx: Latched Writes

=====

Article Created: 15 June 1990  
Article Last Reviewed: 13 July 1992  
Article Last Updated:

TOPIC -----

This article describes Macintosh IIfx latched writes.

DISCUSSION -----

The Macintosh IIfx supports zero wait-state writes to memory by using 64-pin SIMM strips and the new memory-controller technique of latched writes. When the processor issues a write, the memory controller saves the data in a temporary location (the latch, hence the name latched write) and tells the CPU the write has finished (even though it isn't. It lies). The CPU is then free to execute the next instruction. The memory controller then takes data and does a normal write operation. If more data is written out in the next cycle, Page Mode Access is used to write the remaining data.

There are three phases of a latched write. These phases are:

- 1) The processor writes out the data.
- 2) The FMC (Fast Memory Controller) stores the data in the latch and tells the processor the write was completed successfully. The 68030 is now free to execute the next instruction.
- 3) The FMC then writes the data from the latch into system DRAM.

On a normal SIMM strip, the "D In" lines and the "Q Out" lines are tied together. Using 64-pin SIMMs, these lines can be separated and you can have data going in, while using the output bus of the SIMM at the same time. This lets the memory controller implement latched writes and provide zero wait-state writes.

## Macintosh IIfx: Specifications (Discontinued)

Revised: 9/27/93  
Security: Everyone

Macintosh IIfx: Specifications (Discontinued)

Article Created: 19 March 1990  
Article Reviewed/Updated: 13 July 1992

TOPIC -----

This article provides specifications for the Macintosh IIfx computer.

DISCUSSION -----

### CENTRAL PROCESSING UNIT (CPU)

- Microprocessor : 40 MHz MC68030 CPU
- Address Bus : 32-bit
- Registers (32-bit) : 16 general purpose data and address, two 32-bit Supervisor stack pointers, ten special purpose control registers
- Addressing Modes : 18
- 256-byte instruction cache and 256-byte data cache
- Built-in Paged Memory Management Unit (PMMU)

### COPROCESSOR

- MC68882 40 MHz floating-point unit (follows IEEE standards)

### OPERATING SYSTEM

- Macintosh System Software 6.0.5 or later
- A/UX 2.0 (Apple UNIX) or later

### MEMORY

- 4 or 8 MB RAM (Random Access Memory), up to 128 MB using third-party RAM 80ns, 64-pin SIMM
- 4 or 8 MB Parity RAM 60ns, 64-pin SIMM
- Built-in 32K Static RAM Cache, zero wait state operation
- 512K of ROM (Read-Only Memory)
- 256 bytes of parameter memory with built-in battery backup
- Optional Parity Support
- Supports overlapping reads and writes to DRAM

### I/O PROCESSORS

- IOP: Two dedicated I/O processors manage low-level I/O tasks for the serial ports, floppy disk drive(s), and Apple Desktop Bus, providing higher levels of overall system performance.

#### MOUSE

- Apple Desktop Bus Mouse (ADB) mechanical tracking, optical shaft or contact encoding 100 +/- 10 pulses per inch (3.94 +/- 0.39 pulse per mm) of travel

#### DISK DRIVE

- One 1.4 MB high-density (Apple SuperDrive) internal drive. Two internal floppy drives are supported. The unit ships with the SuperDrive, but the logic board also supports an 800K drive

#### HARD DISK DRIVE

- A 3.5" 80MB or 5.25" 160MB hard drive is available

#### INTERFACES

- Two Apple Desktop Bus (ADB) connectors for keyboard, mouse, and low-speed input devices
- Six NuBus Slots supporting full 32-bit address and data lines through a 96-pin EuroDIN connector
- Two RS-232/RS-422 serial ports, 230.4K baud maximum (up to 0.920 Mbit per second if clocked externally)
- SCSI interface
- Stereo sound port for external audio amplifier

#### SOUND GENERATION

- Apple's custom digital sound chip provides 8-bit stereo sampling at 44.1 kilohertz, and includes four-voice wave-table synthesis- capable of driving stereo headphones or other stereo equipment through the sound jack.

#### ELECTRICAL REQUIREMENTS

- Line voltage: 100 to 240 volts AC, RMS automatically configured
- Line frequency: 48 to 62 hertz single phase
- Maximum power consumption: 230 watts maximum (not including monitor power)

#### ENVIRONMENTAL REQUIREMENTS

- Operating temperature: 50 TO 104 degrees F (10 TO 40 C)
- Storage temperature: -40 TO 116.6 degrees F
- Relative humidity: 5% to 95% (non-condensing)
- Altitude: 0 to 10,000 ft (0 to 3048 m)

#### SAFETY AND EMI QUALIFICATIONS

- FCC part 15 Class B Computing Devices
- UL 478 Electronic Data Processing Equipment
- CSA (Canadian Standards Assn.) 220 Information Processing and Business Equipment

#### SIZE AND WEIGHT

- Main Unit

# ..TIL05212-Macintosh\_IIx-Specifications\_Discontinued.pdf

- Height: 5.5 inches (140 mm)
  - Width: 18.7 inches (474 mm)
  - Depth: 14.4 inches (365 mm)
  - Weight: 24 lbs. (10.9 kg) not including hard drive
- Apple Mouse (ADB)
- Height: 1.1 inches (27.9 mm)
  - Width: 2.1 inches (53.3 mm)
  - Depth: 3.8 inches (96.5 mm)
  - Weight: 6 oz. (.175 kg)

## Macintosh IIfx: Input/Output Processors (IOP) Chips

Revised: 7/14/92  
Security: Everyone

Macintosh IIfx: Input/Output Processors (IOP) Chips

=====

Article Created: 15 June 1990  
Article Last Reviewed: 13 July 1992  
Article Last Updated:

TOPIC -----

This article describes the Macintosh IIfx's Input/Output Processors (IOP) Chips.

DISCUSSION -----

The I/O Processor (IOP) is an Apple custom IC designed to provide intelligent support for I/O controllers. There are two of these IOP chips in the Macintosh IIfx computer: one for the SWIM and ADB and one for the SCC. The IOP sits between the main processor and the I/O controllers. The features of the IOP include:

- A built-in microprocessor (6502 running at 2 MHz)
- A 17-bit timer
- Two DMA controllers: one for each serial I/O channel (only used in the Serial IOP)
- Address and data busses for RAM used by the IOP and host processor
- Two digital I/O ports for controlling the ADB (on the SWIM-ADB IOP)
- 32K of external memory of IOP code and data storage

The 68030 communicates with the IOP through a set of control registers in the IOP that are mapped into the main processors' I/O space. The main processor can interrupt the IOP using a bit in one of the control registers, whereas the IOP can interrupt the 68030 by using an interrupt line.

Each IOP has 32K of external RAM that holds the driver and acts as a buffer for the data processed by the processor. The IOP contains a 16-bit auto-incrementing address register and an 8-bit data port that the host processor uses for access to the shared RAM.

## Apple Extended Keyboard II: Specifications (10/94)

Revised: 10/10/94  
Security: Everyone

Apple Extended Keyboard II: Specifications (10/94)

Article Created: 15 June 1990  
Article Reviewed/Updated: 10 October 1994

TOPIC -----

This article provides specifications for the Apple Extended Keyboard II.

DISCUSSION -----

### Description

-----  
The "Apple Extended Keyboard II" is the replacement for the existing Apple Extended Keyboard (M0115). In addition to the features of the existing keyboard, the Apple Extended Keyboard II provides a foot to adjust the height of the keyboard and a double-sided template to label the function keys.

### Packing List (M0312)

-----  
Apple Extended Keyboard II  
1.0 m (3 ft.) ADB cable  
Double-sided overlay to identify function keys  
Owner's guide  
Warranty statement

### System Requirements

-----  
Any Apple personal computer with an Apple Desktop Bus interface

### Technical Specifications

-----  
Total 105 keys, including:

- 18-key numeric pad
- 15 function keys

- Four arrow cursor-control keys in inverted T-style layout
- Six cursor-control keys (Home, Page Up, Page Down, Forward Delete, End, and Help)

#### Size and Weight

-----

|                 |                                     |
|-----------------|-------------------------------------|
| Front Height:   | 0.75 in. (19 mm)                    |
| Rear Height:    | 1.6 in. (41 mm)                     |
| Keyboard angle: | 14 degree maximum, 6 degree minimum |
| Width:          | 18.7 in. (475 mm)                   |
| Depth:          | 7.7 in. (195 mm)                    |
| Weight:         | 4.8 lbs (1.8 kg)                    |

#### Product Details

-----

The keyboard has 15 function keys (F1-F15) and 6 cursor-control keys (home, Page Up, Page Down, Forward Delete, End, and Help).

F1-F4 are labeled on the overlay as follows; F1=undo, F2=cut, F3=copy, and F4=paste. These are not predefined default values; however, developers are being encouraged to use these definitions as appropriate. The remaining 11 function keys can also be defined by the user. An overlay is provided for users to mark the key's function.

The remapping facility is available for a specific application or globally for all applications.

The function keys are operative by using a macro-utility program or by using an MS-DOS application with the appropriate coprocessor card.

The Caps Lock LED is operative in the Macintosh environment. The Num Lock and Scroll Lock are operative in some Macintosh applications. Developers are being encouraged to support these LED's in their applications.

The keyboard has an adjustable foot in the rear of the keyboard. The height of the keyboard is adjusted with a lever in the rear of the keyboard. It can be adjusted with a tilt from the unextended 6 degree to a maximum of 14 degrees from horizontal.

#### Article Change History:

10 Oct 1994 - Clarified LED functionality within the Macintosh environment.

## Macintosh IIfx: Overview

Revised: 7/14/92  
Security: Everyone

Macintosh IIfx: Overview

=====

Article Created: 15 June 1990  
Article Last Reviewed: 13 July 1992  
Article Last Updated:

TOPIC -----

This article gives an overview of the Macintosh IIfx.

DISCUSSION -----

The Macintosh IIfx is an extremely high-speed and elegantly-engineered personal computer that has been designed for people who need the ultimate in Macintosh responsiveness and new Macintosh capabilities.

To provide maximum Macintosh performance and responsiveness, the Macintosh IIfx incorporates a high-speed, 40-megahertz 68030 CPU, a 32K Static RAM Cache memory subsystem, and a 68882 floating-point coprocessor for high-speed program execution and calculations.

The Macintosh IIfx also introduces dedicated I/O processors to the Macintosh family. These custom-designed ASICs (Application Specific Integrated Circuits) boost system efficiency by managing all of the low-level I/O tasks for the Apple Desktop Bus, floppy disk drives, and serial ports. Previously, the 68030 processor had to handle these tasks.

In addition, the Macintosh IIfx contains a dedicated, SCSI, DMA controller that improved SCSI performance.

The Macintosh IIfx supports Macintosh System Software 6.0.5 or higher and A/UX 2.0 (Apple UNIX).

Users who need maximum system expandability will especially appreciate the versatility of the Macintosh IIfx. First, system memory can be expanded from 4 to 8 megabytes with Apple RAM, up to 128 MB with third-party RAM, for high-performance applications that demand superior,

system responsiveness.

Second, the Macintosh IIfx includes six NuBus expansion slots that can accommodate a wide range of Apple and third-party expansion cards, like additional network interfaces and graphics cards. A new Processor Direct Slot (PDS) provides a high-speed interface for third-party hardware options. And six external interface ports accommodate peripherals like hard disks and printers, LocalTalk network connections, and color and gray-scale graphics systems.

For floppy-disk storage, the Macintosh IIfx uses the 1.4-megabyte Apple SuperDrive, which lets users read and write to 3.5-inch Macintosh floppy disks and 3.5-inch disks used in a variety of other personal computers. The Macintosh IIfx also can be configured with up to 160 megabytes of internal hard disk storage. It will also accommodate a second SuperDrive.

Best of all, the Macintosh IIfx is a Macintosh. This means that it still offers all of the benefits of earlier Macintosh systems: access to more than 3,000 of the most powerful, graphics-based applications available; ease of learning and ease of use through a consistent, graphics-based interface; choice without confusion in hardware and software; the convenience of "plug and play" compatibility; and the assurance that all Macintosh components work together smoothly.

## AppleShare File Server v.2.0.x: Concurrent Applications (9/94)

Revised: 9/9/94  
Security: Everyone

AppleShare File Server v.2.0.x: Concurrent Applications (9/94)

=====

Article Created: 27 February 1990  
Article Reviewed/Updated: 9 September 1994

TOPIC -----

How many applications can run concurrently on an AppleShare File Server version 2.0.x?

DISCUSSION -----

The AppleShare File Server v.2.0.x software allows for one foreground application to be active at any one time. Examples of foreground applications include the AppleShare Admin program and the AppleShare Print Server. The AppleShare File Server v.2.0.x software has no knowledge of background applications, like Microsoft Mail, InBox, QuickMail, and the AppleTalk Internet Router. Therefore, it cannot place any limit on the number of applications running at a given time.

It is possible to set up an AppleShare File Server v.2.0.x with the AppleShare Print Server running in the foreground and several other applications running in the background. It is important to note that more memory may be required on a file server that has several applications running in the background. If you are going to have several background applications, it is important to test them together on a file server to verify that they do not conflict with each other or cause random system crashes. Also, each application running in the background takes up CPU time and will affect the overall performance of the file server. If many background applications are running, one or more of them may fail due to lack of CPU time.

Article Change History:  
09 Sep 1994 - Added notation of version 2.0.x of AppleShare File Server.

## HyperCard: Where To Get AppleTalk XCMD Programming Help

Revised: 6/24/90  
Security: Everyone

HyperCard: Where To Get AppleTalk XCMD Programming Help

=====

This article last reviewed: 27 February 1990

TOPIC -----

I want to write an XCMD to find all of the available nodes on a network. I read in "Inside AppleTalk" about GetZoneList and ReceiveZoneList, but I'm not sure how to access these calls in my program. Can you help?

DISCUSSION -----

On AppleLink, there is sample source code, in Pascal, that demonstrates how to use the ZIP command "GetZoneList". Here is the path (available to all AppleLink subscribers):

Developer Services  
Macintosh Developer Technical Support  
Sample Code  
SC.011.GetZoneList

Also, APDA sells a product called "HyperCard AppleTalk Toolkit v. 2.5" that includes XCMDs, XFCNs, and source code (in C) for accessing AppleTalk networks. However, none of these XCMDs or XFCNs implements ZIP (Zone Information Protocol). For more details, search the Technical Info library under "APDA."

## Macintosh: IBM Host File Transfer and EIS (8/94)

Revised: 8/30/94  
Security: Everyone

Macintosh: IBM Host File Transfer and EIS (8/94)

Article Created: 27 March 1990  
Article Reviewed/Updated: 30 August 1994

TOPIC -----

I have both an AS/400 and 3090. I want to extract information from a database on the AS/400 and download it to the Macintosh, importing it into 4th Dimension.

- 1) Do IBM mid-range machines support IND\$FILE?
- 2) What is the "standard" way to download data from an AS/400? Does KMW (or any other vendor) support this method? How can data be downloaded to the Macintosh?
- 3) What types of 5250 terminals are there?
- 4) When the site has ASCII-attached terminals to the AS/400, are they still doing 5250 emulation, or is it just TTY?
- 5) Are applications written for the Twinax-attached 5250 terminal compatible with the ASCII-attached terminals?
- 6) I am also interested in using a Macintosh as an EIS, emulating a 3270-type terminal to front-end their 3090. Does Avatar have HyperCard XCMDs to work with their API to handle 3270 sessions? What is the extent of services offered by these XCMDs? Can they be used to completely bypass the terminal emulation software. That is, can they log on to the host, choose host menus, extract data, and so on, through HyperCard?

DISCUSSION -----

- 1) The AS/400 doesn't support IND\$FILE.
- 2) The standard way for an IBM PC or PC-clone to download files is via the program PC Support, which offers LU62 connectivity for PCs.

Because there isn't a Macintosh equivalent offering a virtual disk attachment, the typical way one transfers files is by using the IDEAssociates, KMW (now Andrew Corp.), or Wall Data terminal emulators. Each has its own proprietary file transfer capabilities. Some manipulation of the file delimiters may be desired before downloading and importing into 4th Dimension. Such a report typically would be set up by the AS/400 system programmer.

3) The terminal types are Models 2-4, color, but, in general, these 5250 terminal types are being replaced by the newer 319x types, referenced in articles in the Tech Info Library.

4) ASCII-attached terminals are probably still considered a 5250-type terminal while running a VT100 emulator.

5) The mainframe applications usually don't care whether you have a Twinax- or serial-connected terminal.

6) A number of terminal emulation manufacturers offer HyperCard-based API toolkits for 3090s, including Avatar (now DCA), Tri-Data (now DCA), and DCA, which would be ideal for an EIS (Executive Information System). All have the log on feature or are capable of logging on to hosts and providing the other features you request. Because they are HyperCard-based, they are more easily customized and extended to incorporate any specific features required.

Here are some general observations on KMW (now Andrew Corp.), IDEAssociates, PCI, and Wall Data.

To locate a vendor's address and phone numbers, use the vendor name as a search string.

Andrew Corp. provides products consisting of hardware and software to connect to both the AS/400 and System 3x computers. They call their system "Series II Twinax."

IDEAssociates provides connections between the AS/400 computers and the System 3x computers. IDEAcomm Mac is the name of the package from IDEAssociates.

PCI makes SmartLink 5250/MacCom, a hardware protocol converter (Twinax or remote) and software to connect Macintoshes to AS/400 and System 3x computers.

Wall Data provides products consisting of software to connect to both IBM midrange and mainframe computers. The SNA•ps product family provides both terminal and print emulators.

## HyperCard: Telephone Interface and Auto-Dialing Packages

Revised: 6/24/90  
Security: Everyone

HyperCard: Telephone Interface and Auto-Dialing Packages

=====

This article last reviewed: 27 February 1990

TOPIC -----

I want to use a Macintosh to keep telephone directories of people and click on a button to dial their phone numbers.

My office (in a school) has a AT&T Merlin telephone system. Is there any hardware (other than HyperDialer) that can do this? Will it support multiple lines?

Other than HyperDialer or using a modem to do the dialing, what other kinds of products exist to do dialing from the Macintosh?

DISCUSSION -----

There are a few other hardware phone interface products, but none with built-in support to connect and arbitrate among multiple lines. However, none is prevented from using different lines if used with the appropriate interfacing module. Being able to choose multiple lines is usually a function of the telephone system and the handsets or interfacing modules connected to it.

The only interfacing module available for the Merlin System to connect modems, facsimiles, autodialers, or answering machine-type devices is the General Purpose Adapter sold by AT&T. (AT&T also sells expansion modules for creating modem pools.)

You could use one of the HyperDialer-type products to connect to the General Purpose Adapter. When combined with a HyperCard stack or database of your own design or one of the commercial programs available, you could do what you describe.

Some programs and products are listed below, but many other programs, including high-end and sophisticated products (these telemarketing products can cost thousands of dollars), are listed in the various buyers guides and on AppleLink

(in the electronic buyer's guides).

Here are some products worth looking into:

School Administrator's Assistant from Chancery Software, Ltd.

-----  
The School Administrator's Assistant is a HyperCard stack that helps a user manage routine tasks.

The School Administrator's Assistant maintains staff information (including job descriptions, certification, objectives, and appraisals); prints a variety of reports; documents pupil behavior incidents and streamlines suspension paperwork; plans daily, weekly, and monthly activities with a reminder system; maintains an address and telephone directory; dials telephone numbers and keeps a record of calls; links information to word processing applications via mail-merge capabilities; searches and browses through data maintained in the stack; maintains memos and notes; sets password access to sensitive information; maintains a pool of pupil information; searches, sorts, organizes, and prints transportation information; and launches frequently-used programs and documents from within the stack.

HyperCable from Caseys' Page Mill

-----  
HyperCable is an audio connector that lets you dial a telephone from a Macintosh. It plugs into the audio output jack on the rear of a Macintosh and into the telephone jack. HyperCable works with HyperCard.

HyperDialer from DataDesk International

-----  
HyperDialer is an automatic telephone dialing device that autodials any telephone number from HyperCard or from HyperCard stackware. It connects to the audio port on any Macintosh and can be connected to any telephone, including multi-line business phones, in less than a minute. HyperDialer eliminates the need for a modem or dedicated phone line for automatic dialing.

The BTM HyperCard Hands-Free Phone Dialer System from Business Technology Manufacturing, Inc.

-----  
Directly connects the "real world" of telephones and telemarketing to the Macintosh and programs, like HyperCard, FocalPoint, Microsoft Excel, and Microsoft Works; used with a telephone or headset. The system has two modes of operation: Hands-Free and HeadSet. It comes with all hardware and stackware needed.

In the Hands-Free mode, users simply touch the telephone icon, and they will hear the dialtone, the touch-tones as they are dialed out, and the ringing or busy signal--all without picking up the handset. When contact with the dialed party is established, picking up the handset automatically disconnects the dialer from the line and normal operation of the phone continues.

The addition of an operator-type headset turns the dialer into a complete telephone. In this mode, complete control of the dialer is from the Macintosh screen with many added features, such as Mute, Hold, Flash, Auto Redial,

Dialer-On and Dialer-Off.

The dialer connects directly to the phone line using a standard RJ-11C phone jack, which is provided with the unit. Multi-line pushbutton and ComKey adapters are available as an option.

## AppleShare Print Server: Using a Macintosh 512Ke as a Server

Revised: 6/24/90  
Security: Everyone

AppleShare Print Server: Using a Macintosh 512Ke as a Server

=====

This article last reviewed: 27 February 1990

TOPIC -----

Will a Macintosh 512Ke with 1MB RAM support five printers as an AppleShare Print Server? If not five, how many will it support? The manual refers only to Macintosh 512K configurations.

DISCUSSION -----

A Macintosh system with 1MB RAM can capture up to five printers or two if an AppleShare File Server is running on the same machine.

A 1MB Macintosh 512Ke is not mentioned in the AppleShare Print Server manual, because Apple did not make or sell 1MB Macintosh 512Ke systems.

## Macintosh II: Math Coprocessor Can Be Upgraded to MC68882

Revised: 7/20/92  
Security: Everyone

Macintosh II: Math Coprocessor Can Be Upgraded to MC68882

=====

Article Created: 27 February 1990  
Article Last Reviewed: 20 July 1992  
Article Last Updated:

TOPIC -----

A third-party supplier told me that I can improve performance of my Macintosh II by upgrading the MC68881 math coprocessor to a MC68882. Is this correct?

Isn't the MC68881 optimized for use with the MC68020 in the Macintosh II? Would using a MC68882 with a MC68020 produce compatibility problems with some software expecting a MC68881? Is an upgrade advisable?

Likewise, can a MC68881 be used with the MC68030, or should the MC68882 always be used? What are the performance issues related to cross-matching CPUs and math coprocessors?

DISCUSSION -----

The MC68882 Floating Point Unit (FPU) is a superset of the MC68881 and is software- and hardware-compatible with the MC68881 FPU. Generally, the MC68882 is 1.5 to 2 times faster than the MC68881.

The December 1987 issue of "Byte" has a two-page article (pages 120 and 121) testing the Motorola MC68882 math coprocessor chip. The tests show that with the MC68882 installed in a Macintosh II, benchmarks execute from 4 to 22% faster than with the MC68881. Installation in the Macintosh II is done by swapping chips.

The MC68881 can be used with the MC68030. The only concern here is that some software may be written to take advantage of the new features that the MC68882 provides. We can see no reason why you would have a Macintosh system with this combination, so no problems should arise.

## LaserWriter IINT: -8132 Error Is Manual TimeOut Error

Revised: 6/24/90  
Security: Everyone

LaserWriter IINT: -8132 Error Is Manual TimeOut Error

=====

This article last reviewed: 27 February 1990

TOPIC -----

What is a -8132 error? I get it once in a while when I'm doing a large (200) envelope print merge to a LaserWriter IINT using Microsoft Works 2.0. When an envelope misfeeds and jams the printer (which happens with great frequency), by the time I pull out the paper tray, remove the jammed envelope, and open and shut the top to clear the error, one of two things happens:

- The print merge (which doesn't create a temp file) drops several envelopes.
- The print job aborts, displaying a dialog box with the message "Printing error -8132."

I've looked at the error codes sections in "Inside Macintosh", "Inside AppleTalk", and called Microsoft. They claim it is a network error, but I didn't find it in "Inside AppleTalk".

DISCUSSION -----

The error -8132 means "manual timeout error", which, applied to your situation, fits perfectly. Once you manage to keep the LaserWriter from jamming on the envelopes, you should no longer experience this error.

## Full Impact: Steps to Recover a Corrupted File

Revised: 6/24/90  
Security: Everyone

Full Impact: Steps to Recover a Corrupted File

=====

This article last reviewed: 27 February 1990

TOPIC -----

I am having a problem when editing a Full Impact 1.1. file. The file is a weekly report, which is a spreadsheet containing data, formulas, paragraphs, and charts. I update the information weekly to generate a new weekly report. Updating includes changing the date, data, and charts and recalculating the formulas. For several weeks, I had been doing the updating without any problem. However, today, the system froze when I tried to change the date.

Specifically:

- 1) I opened the file.
- 2) I clicked on the cell containing the date information.
- 3) I edited the date.
- 4) I pressed the Return key.

Normally after pressing the Return key, the active cell is the cell below the Date cell. However, this time the screen froze and stopped at the same Date cell. The arrow pointer was still working. That is, it was free to move around the screen. I typed Command-period, but nothing happened. The only way to clear the screen was to restart the system.

I also tried this on other cells, and the same thing happened.

Do you have any idea what caused this problem?

DISCUSSION -----

We suspect that the file has become corrupted, but before throwing it away, you may want to try these steps:

- 1) Open the damaged file, save a copy under a different name, and try to use the copy.
- 2) Re-install the System Software.
- 3) Repair the volume the file is stored on using Disk First Aid or a similar program.
- 4) Since the system crashed, try rebuilding the Desktop file by holding down the Option and Command keys while restarting.

If these steps don't help, you may be able to copy the information from the old spreadsheet, and paste it into a new one. If you have to recreate the spreadsheet, you might want to print copies of the spreadsheet, both the values and the formulas (this is possible with Microsoft Excel and other spreadsheets, and we assume it is possible to print formulas with Full Impact, too).

## FileMaker II: Multi-user Crash Recovery

Revised: 6/16/92  
Security: Everyone

FileMaker II: Multi-user Crash Recovery

=====

Article Created: 28 February 1990  
Article Last Reviewed: 27 May 1992  
Article Last Updated: 27 May 1992

### TOPIC -----

A database was set up using FileMaker II 1.1.2 for multi-user access. A Macintosh Plus logged on to the database as a guest. In the process of printing some reports with this database, this system bombed (with the dialog box requesting a "Restart"). At this point, the address of this system was still registered as being connected to the database as a guest. As a result, it was not possible for the host of this database to log off because it requires all the guests to log off from the database before the host can quit.

After the system was restarted and logged on to the database again, the number of systems logged on to that database increased by one. That is, the previous address ID of this system still remained.

How can I remove the address of the Macintosh Plus that bombed? Is there a better way of using multi-user access so that this problem won't happen again?

### DISCUSSION -----

When you log onto FileMaker II again as a guest and then quit, your current entry, and the original, will be removed, allowing the host to shut down. However, until the guest logs on and quits, there are no options within the program allowing the host to quit FileMaker II. Resetting the host's system, or terminating the process with a debugger, if it is running MultiFinder, are poor but effective alternatives.

For more information about this issue, contact Claris directly. Meanwhile, you may want to investigate why the guest's system is crashing to minimize the impact it has running FileMaker II.

## Macintosh IIci: Launching Microsoft Word 4.0 Causes Bomb

Revised: 7/9/92  
Security: Everyone

Macintosh IIci: Launching Microsoft Word 4.0 Causes Bomb

=====

Article Created: 27 March 1990  
Article Last Reviewed: 8 July 1992  
Article Last Updated: 28 March 1991

TOPIC -----

A customer has a Macintosh IIci with System Software 6.0.4 on a network using a 3COM card running AppleTalk Phase 2. Occasionally, when launching Microsoft Word 4.0, his system locks. This happens approximately 50% of the time. The exact same setup on his Macintosh IICx does not produce the problem.

RESPONSE -----

Microsoft Word, version 4.00b or later fixes the compatibility problem with the Macintosh IIci. All Macintosh IIci users should upgrade their copy of Microsoft Word to version 4.00b (or later). Apple also recommends that Macintosh IIfx, Macintosh LC, Macintosh Classic, and Macintosh IIsi users upgrade to version 4.00b (or later). This upgrade is available by calling Microsoft Customer Service. To locate a vendor's address and phone numbers, use the vendor name as a search string.

The problem details are:

Microsoft uses a synthetic handle (a "fake" rgnHandle) when doing certain operations involving drawing icons in the menu bar. The new, 24-/32-Bit Memory Manager in the Macintosh IIci does additional error and validity checks on all handles that it operates on. Due to Microsoft Word's placement in memory, this may cause a variety of apparently random crashes.

Often fake handles, built on the stack, point into I/O space if these handles have been incorrectly translated by the Memory Manager. The read access made to validate its zone header is probably what's causing the crashes. The Memory Manager does load a bus error handler on unused NuBus

slots, so when the machine crashes, it is probably because the fake region is pointing at his 3COM card.

## Macintosh IIfx/Portable: Crash May Be Caused by WDEF Virus

Revised: 6/24/90  
Security: Everyone

Macintosh IIfx/Portable: Crash May Be Caused by WDEF Virus

=====

This article last reviewed: 28 February 1990

TOPIC -----

Is there any history of floppy-disk errors occurring under System 6.0.4 that take the system down?

I been experiencing random system crashes (ID=0) when inserting or ejecting floppy disks. The disks are readable on systems running System 6.0.3, and the problem seems to appear only on the Macintosh IIfx and Macintosh Portable.

I've rebuilt the desktops of the hard drive and the floppy disks, but the problem continues.

Is this problem characteristic of the WDEF virus? Is it likely that they are reinfecting their systems? Or is there another reason why this problem seems to be confined to the new machines?

DISCUSSION -----

There isn't a history of disk errors that cause any system to bomb. However, as you mentioned, the symptoms are characteristic of a WDEF virus infection on a Macintosh IIfx or Macintosh Portable. It is possible you are reinfecting your own systems. Perhaps if you are reinfecting your systems, you should acquire a virus interception program and run a virus detection program routinely.

## AppleShare: Updating From Version 1.1 to 2.0

Revised: 6/24/90  
Security: Everyone

AppleShare: Updating From Version 1.1 to 2.0

=====

This article last reviewed: 28 February 1990

TOPIC -----

If an AppleShare volume has been prepared using an earlier version of AppleShare (pre-2.0), will AppleShare 2.0 be able to recognize that volume, or will it prompt the user with the "Do you want to prepare this volume for use with AppleShare" message? If so, and the user selects "OK", does the existing users/groups file get replaced by a new one, or simply get updated to work with the new version of AppleShare?

DISCUSSION -----

Complete information about updating an AppleShare File Server from version 1.1 to 2.0 is outlined in chapter 5 of the AppleShare File Server Administrators Guide shipped with AppleShare 2.0.

In answer to your specific questions:

- 1) Yes, the administrator will be prompted to prepare the volume(s) for use with AppleShare.
- 2) No, the users/groups file will not be replaced and, therefore, will not affect any folder access privileges.

## Macintosh-to-AT&T 3B2 Solutions (9/94)

Revised: 9/13/94  
Security: Everyone

Macintosh-to-AT&T 3B2 Solutions (9/94)

=====

Article Reviewed/Updated: 12 September 1994

TOPIC -----

A customer wants to connect Macintoshes to an AT&T 3B2 multi-user, UNIX-based machine. The customer wants terminal emulation, file transfer, and E-mail compatibility. Apparently, terminals are now connected with coax. I am still trying to get the actual name and version of the E-mail package they are using. Do you know of any solutions in this environment? The MultiVendor Solution Guide does not list AT&T equipment, and I did not find the information in the Tech Info Library. Any help will be greatly appreciated.

DISCUSSION -----

The AT&T 3B2 is an AT&T System V-based, multi-user UNIX machine, and our A/UX is an AT&T System V.2.2 multi-user UNIX machine. Since UNIX is a general-purpose time-sharing system, it contains a full scope of capabilities, like:

- Multi-user, multitasking ability
- A wide variety of software development
- Device-independent input and output
- Inter-Process Communication (IPC)
- Network protocols (TCP, IP, UDP, ICMP, SMTP, and so on)
- File transfer and remote login (FTP, Telnet, RLOGIN, and so on)
- NFS (Network File System)

On the UNIX side, A/UX can satisfy the customer's need for terminal emulation, file transfer, and E-mail. Terminal emulation lets you log on to a UNIX machine from different types of terminal--like VT100, VT52, ANSI, and so on. The file transfer methods include "ftp", "rcp", "nfs", and "uucp", for example. The

popular E-mail mechanism is "sendmail", using SMTP protocol.

On the Macintosh side (Macintosh OS), there are many ways to connect a Macintosh to an AT&T 3B2 (or, virtually, any UNIX machine), while providing terminal emulation, file transfer, and E-mail.

For terminal emulation and file transfer, the new version of NCSA Telnet ("ftp" and "telnet") along with MacTCP can be used via Ethernet. If the 3B2 supports X Window System and a client application, like "xterm", MacX (an X server) can be used for remote login sessions. If no Ethernet or LocalTalk is involved, the terminal emulation can be done using any popular terminal emulation program--like MacTerminal, MacPhone, and others--via the modem serial port (hard-wired or modem/phone line).

For E-mail capability between a Macintosh and a 3B2 UNIX machine, QuickMail for the Macintosh probably can send and receive both UNIX mail and QuickMail from a Macintosh or a UNIX machine. QuickMail is a product of CE Software. For more details, search the Technical Info library under "CE Software."

## Apple IIf Plus: Use Revised IIf Technical Reference Manual

Revised: 6/24/90  
Security: Everyone

Apple IIf Plus: Use Revised IIf Technical Reference Manual

=====

This article last reviewed: 28 February 1990

TOPIC -----

A customer needs technical information on the Apple IIf Plus. Is there an "Apple IIf Plus Technical Reference" available or will one be published soon? Are there any other technical publications for this particular system?

DISCUSSION -----

The "Apple IIf Technical Reference Manual, Second Edition" from Apple Computer is available from APDA. This publication includes sections specific to the Apple IIf Plus, unlike the original Addison-Wesley edition. The part number is A2G0052/A; the "/A" indicates the second edition. For more details, search the Technical Info library under "APDA."

We don't know of any other technical publications specifically for the Apple IIf Plus.

## Macintosh: Information on Array Processors

Revised: 6/24/90  
Security: Everyone

Macintosh: Information on Array Processors

=====

This article last reviewed: 28 February 1990

TOPIC -----

I need some information about array processors.

- 1) What are their primary functions?
- 2) Who makes them?
- 3) Does the Macintosh interface with them?
- 4) Do you have any pricing information?

DISCUSSION -----

- 1) Array processors are used to process math arrays. This is particularly helpful when working with three-dimensional objects. Three-dimensional objects are described in arrays and manipulated with matrix multiplication. Array processors are designed to expedite these array transformations.
- 2) Mini and mainframe manufacturers and related third-party companies manufacture array processors.
- 3) We don't know of any array processors for the Macintosh.
- 4) We have been unable to locate prices for these minicomputer and mainframe products.

The only products that come close are generic accelerators for the Macintosh. These are not the same type of product as the array processors, but increasing the speed of computation, in general, appears to be the only possibility for increasing the array processing desired.

## Serial NB Card: Use with Multiple Modems (5/96)

Revised: 5/31/96  
Security: Everyone

Serial NB Card: Use with Multiple Modems (5/96)

Article Created: 24 April 1990  
Article Reviewed/Updated: 30 May 1996

TOPIC -----

I want to connect multiple modems to my Macintosh. I know that I can do this with the Serial NB Card, but is there software to support it?

DISCUSSION -----

Apple Remote Access Multiport Server uses the Serial NB card to connect 4 modems for Remote Access connections. The Multiport Server software can support additional Serial NB cards expanding the modem ports even further. The limit will depend on the number of NuBus slots in your Macintosh.

For a non-ARA solution, Apple has software for the Serial NB Card, however, most often its the applications that do not support multiple modems. They use only one port of the card.

You could use any telecommunications application that can operate in the background under MultiFinder. MicroPhone II version 3.0 lets several copies run under MultiFinder. The three issues involved are:

- Background operation
- The ability to work with NuBus-based serial ports
- Each copy is using a separate serial port

The publisher of MicroPhone II, Software Ventures, suggests checking with their technical support group when trying to use NuBus serial cards. This is a good suggestion for any telecommunications application that may be used in this situation--not every application currently provides support for NuBus serial cards.

Article Change History:  
30 May 1996 - Corrected minor typographical errors.

## Macintosh Portable: System 6.0.5 Fixes Excessive Battery Drain

Revised: 2/1/91  
Security: Everyone

Macintosh Portable: System 6.0.5 Fixes Excessive Battery Drain

=====

This article last reviewed: 8 January 1991

TOPIC -----

A problem has been discovered with the Macintosh Portable that relates to reduced battery power.

When the Macintosh Portable has AppleTalk active (in the Chooser) and you select the "Shut Down" command, the SCC chip continues to draw excess current from the battery. If the machine is not used for 4 or more days, the battery will be drained and need a recharge. (Normally, the Macintosh Portable's charge will last about 4 weeks when stored in the shutdown condition).

This problem does NOT occur when AppleTalk is active and the "Sleep" command is selected instead of "Shut Down." This problem also does NOT occur if AppleTalk is inactive and "Shut Down" is selected.

DISCUSSION -----

This problem was corrected with System Software 6.0.5. We recommend that you upgrade to System Software 6.0.5 or later.

## EtherTalk 2.0.1: Improves Copy Performance

Revised: 6/29/90  
Security: Everyone

EtherTalk 2.0.1: Improves Copy Performance

=====

This article last reviewed: 2 March 1990

TOPIC -----

I'm having a problem when performing a Finder copy to an AppleShare File Server on an EtherTalk network. If you narrow the network down to a 2-node EtherTalk 2.0 network, you get these following results:

Copying a 3.3MB folder to a Macintosh II varies between server with an internal HD160 SC, the copy time 113 seconds to 700+ seconds using the same drive on different Macintosh II computers. The time varies on a single machine and across machines. Using the same drive in a Macintosh IIX, the same copy process consistently takes 48 seconds. When an internal 40MB drive was used on the offending machines, these problems were not observed.

- 1) Why does the time vary?
- 2) Why is the time for the HD160 SC so much slower than those we saw on the HD40 SC?
- 3) Why isn't the Macintosh IIX demonstrating the same problems?

DISCUSSION -----

We were able to duplicate this problem with some interesting twists. In our case, the slower machines were the Macintosh IIX systems with a particular Macintosh II performing as you would expect. Furthermore, HD80 SC drives also exhibited these symptoms.

In our tests, we found that the results varied from machine to machine and hard drive to hard drive, so we have concluded that the problem is not with particular hardware.

The problem can be resolved by upgrading to EtherTalk 2.0.1. When we did this, all drives on all machines functioned as expected. We recommend that all

machines (workstations and servers) be upgraded to EtherTalk 2.0.1.

## LaserWriter: Print Manager Calls for Selecting Print Driver

Revised: 7/16/90  
Security: Everyone

LaserWriter: Print Manager Calls for Selecting Print Driver

=====

This article last reviewed: 2 March 1990

TOPIC -----

I am writing code in MacApp and have a question on the Print Manager. I have figured out how to use the value of a variable to determine if the printer chosen by the user is a LaserWriter or ImageWriter. However, I can't tell if it is a PostScript LaserWriter, a LaserWriter IINT, LaserWriter IINTX, or a LaserWriter IISC. What I need are the calls to determine if the chosen printer is a PostScript printer or not. The reason they need this information is that in their program they are printing encapsulated PostScript files. They want to display a dialog box warning users if they are going to a non-PostScript LaserWriter, they will not be able to print that image.

DISCUSSION -----

You can get the information on what printer driver has been selected by inspecting the value of the fLastPrinterName field of the TStdPrintHandler object belonging to the view you are trying to print. The fLastPrinterName field is changed to reflect the printer driver most currently selected in the Chooser when a Print or Page Setup command is issued. For the LaserWriter IISC print driver, the value of this field is "LaserWriter IISC." If a network-based printer is chosen using the LaserWriter driver, the field contains "LaserWriter."

## MS-DOS Word/Works: Printing Problem and Fix

Revised: 11/14/90  
Security: Everyone

MS-DOS Word/Works: Printing Problem and Fix

=====

This article last reviewed: 12 November 1990

TOPIC -----

Microsoft and Apple have worked to resolve the problems of printing from Microsoft Word 5.0 for the PC to an AppleTalk LaserWriter or Print Server. (Users of Microsoft Works 2.0 for the PC may encounter the same problem and take advantage of the same solution outlined below.)

Microsoft will support these changes and plans to complete and distribute a new driver in the future.

### The Problem

-----

When using a spooler, users can't print (in PostScript mode) from within AppleShare PC. If a spooler is not involved, a user can print once without turning the LaserWriter off and then on.

This is because Microsoft sends two print jobs at one time--the first is the initialization file; the second is the user's print job. They are separated by a Control-D, the PostScript end-of-file character. The first part loads a permanent dictionary into the LaserWriter's memory. It works fine the first time. The second time a user prints, the LaserWriter sends a message to AppleShare PC saying that the print job is aborted (because the dictionary is already loaded). AppleShare PC then quits, and the second half (the user's file) of the job doesn't print.

DISCUSSION -----

The solution is to modify Microsoft's POSTSCR.PRD and POSTSCR.INI files.

In order to print Microsoft Word 5.00 documents to an Apple LaserWriter through the AppleShare Print Server's spooler, you must modify Word 5.00's POSTSCR.PRD print driver and POSTSCR.INI initialization file.

Modifications to POSTSCR.PRD:

You must first convert this binary file into a text file by running the MAKEPRD.EXE conversion utility provided with Word 5.00. For more information on running MAKEPRD.EXE, consult Chapter 6, Using the MAKEPRD Program, in the "Printer Information for Microsoft Word" manual.

1. Use MAKEPRD to convert POSTSCR.PRD from a binary file into a text file.
2. Start Word and load the text file created by MAKEPRD.
3. Use the Search command to locate the text string "byte:0". The cursor will now be located on a line that reads:

```
byte:0 mod:0 "%!PS-Adobe-2.0 ^M^JPSp"
```

Remove the "%!PS-Adobe-2.0" header so the line reads:

```
byte:0 mod:0 "^M^JPSp"
```

4. Save the file as a text-only file, then quit Word.
5. Convert the modified textg file back into a binary file with MAKEPRD.

Modifications to POSTSCR.INI:

1. Start Word and load POSTSCR.INI.
2. Remove line 1. This line reads: %!PS-Adobe-2.0 ExitServer]
3. Remove lines 8 through 15, which look like the following:

```
%%BeginExitServer:0
userdict/msinifile known
{msinifile (POSTSCR) eq {stop} if} if
serverdict begin 0 exitserver
userdict/msorigstate know {msorigstate restore} if
save/msorigstate exch def
/msinifile (POSTSCR) def
%%EndExitServer
```

4. Modify the /PSI definition (line 21) by adding the PostScript command "Initmatrix" after the capital E and before the "90" so the line reads:

```
def fonttable 1 get fontset E initmatrix 90 rotate 0-612 translate
```

5. Modify the /PSP definition (line 25) by adding the PostScript command "Initmatrix" after the capital E and before the "save" command so the line reads:

```
def fonttable 1 get fontset E initmatrix save statusdict begin
```

6. Use the Search command to locate the text string "/PSe". Remove the command "currentfile closefile" from the line so it reads:

```
/PSe {restore end} bind def
```

7. Move to the end of the file by pressing CTRL-PGDN. Delete the first CTRL-D (diamond shaped) character.

8. Save the file as a text-only file.

The POSTSCRIP.PRD and POSTSCRIP.INI files should now be compatible with the Appleshare Print Server.

## Third-Party Scanners: Macintosh Compatible

Revised: 6/24/90  
Security: Everyone

Third-Party Scanners: Macintosh Compatible

=====

This article last reviewed: 2 March 1990

TOPIC -----

Is there a Macintosh-compatible scanner that scans 11 x 17 ink documents (like floor plans)?

DISCUSSION -----

You might look into the following products:

Houston Instrument's DMP-60 Series are professional, drafting-pen plotters that have a resolution of 0.0005 inches, accuracy of +/- 0.010 inches, and support HPGL and DM/PL. The DMP-61 plots at 32 inches per second axial speed and handles media from ANSI A to D sizes. The DMP-62 plots at 24 inches per second axial and handles media from ANSI A to E sizes. Both models accept the following options: MP-80 eight- pen changer, the Scan-CAD optical scanner accessory, a Kanji character set board and a 1MB expanded internal buffer.

Sharp Electronics's JX-450 Professional Color Scanner can scan images up to 11 by 17 inches in 24-bit color, 256 gray scales and monochrome. The scanning resolution of 300 dpi is adjustable from 30 to 300 in increments of one. An optional mirror unit lets users scan 35mm slides and transparencies up to 8.5 by 11 inches. The JX-450 uses a GPIB (IEEE 488) interface.

Howtek's Scanmaster is a flatbed scanner that provides an effective way of converting hard copy color images into data that can be entered into an image-capturing computer. It allows a user to store, modify, and enhance color images. Input copy can be in the form of line art, text, continuous tone, or halftone documents.

The Scanmaster scans continuous-tone and half-tone images up to 11 by 17-inches and film transparencies up to 8 by 10-inches.

The Scanmaster employs a single CCD sensor and an all electronic Red-Green-Blue

(RGB) color separation method. It digitizes full-color or black and white images or color transparencies at 30 to 300 dpi and transmits the data over a GPIB interface.

Application software is also provided. A menu-driven package, Scan-It, provides immediate access to all of the scanner's features. Using a pull-down menu, a user can select an area to scan, zoom, crop, and size the image. A contrast and color correction menu lets an operator adjust the gamma correction (contrast) in the scanner to match a specific output display device and to color correct an image by modifying the scanner's internal color look-up tables (LUTs).

You can output color-corrected and sized images to one of three file formats: PICT II, RIFF (Raster Image File Format), and Howtek's SIM (Scanned Imaged file format).

## AppleShare PC: Bitmapped Graphics With Epson LQ2500

Revised: 6/24/90  
Security: Everyone

AppleShare PC: Bitmapped Graphics With Epson LQ2500

=====

This article last reviewed: 2 March 1990

TOPIC -----

I have migrated from TOPS to AppleShare. I have a program written in BASIC that prints a form with half-graphic characters on MS-DOS.

This works fine with TOPS Netprint. However, I couldn't get this form to print with AppleShare. The half-graphic characters are converted. AppleShare PC has the Epson LQ2500 command set, and Netprint has the Epson FX80 command set. What exactly are the differences?

DISCUSSION -----

The Epson LQ2500 command set is a superset of the command sets belonging to the Epson LQ1000, LQ800, LQ1500, EX series, FX series, LX series, RX series, MX series, Epson printer, Standard printer, and Draft printer. Your problem is not due to a command set difference; it is with the IBM graphics character definitions and those of the ASCII character set defined by AppleShare PC.

You are using IBM graphic text characters, which are not a part of the LaserWriter's PostScript or the U.S. Standard ASCII character sets. Unfortunately, the characters defined for use by AppleShare PC stop at ASCII value 176. The graphic characters of the IBM character set begin at a higher value within the ASCII range.

Page 104 of the "AppleShare PC 2.0 User's Guide," shows the characters available from the Epson LQ2500 AppleShare PC option. Printing Epson graphics while using AppleShare PC Epson option does work. A program printing through AppleShare PC must use bitmapped graphics to generate lines or other graphics when using the Epson LQ2500 option.

There are a couple of possible workarounds that the TOPS Netprint program may have used to avoid this situation. The optional symbol set within the LaserWriter does include some horizontal and vertical line symbols. These may

have been mapped into the same characters used by your customer's program. You can also create new character definitions within PostScript, and the IBM characters may have been recreated and defined as part of the LaserWriters ASCII character set.

AppleShare PC does not include either of these options for printing IBM graphic characters. We can only suggest that you use a program that prints bitmapped graphics for its form design or use TOPS Netprint.

## A/UX: sleep and Flow Control Settings

Revised: 9/24/92  
Security: Everyone

A/UX: "sleep" and Flow Control Settings

=====

Article Created: 5 March 1990

### Article Change History

-----

08/31/92 - REVIEWED  
o For technical accuracy.

### TOPIC -----

A colleague told me that I needed to use the "sleep" command with the "stty" command when doing modem settings. He said that the purpose of "sleep 3600" is to force the tty to stay open, so that the later "cu" command can take effect with changed settings.

However, I was under the impression that flow control settings are maintained across last close (unlike the standard SVID termio settings) and therefore, don't need "sleep". Who's right?

### DISCUSSION -----

You don't have to issue the sleep command to keep the tty open. You are right as far as you go; the flow control settings are maintained across last close, unlike the standard SVID termio settings.

All tty flow control characteristics, like "modem", "-modem", "dtrflow", "-dtrflow", and so on, are maintained across last close. This means the flow control settings are "remembered" when a tty device is closed and reopened. However, all other termio characteristics, like speed (50, 75, 1200, and so on), parity (parenb, parodd), input modes (ignbrk, brkint), and so on, are set to the default settings when the tty line is closed.

Therefore, a statement like "sleep 3600" in a modem setting is not required, but for other settings, like the speed change, it is necessary.

## A/UX: Connecting to TCP/IP and NFS Network (9/94)

Revised: 9/2/94  
Security: Everyone

A/UX: Connecting to TCP/IP and NFS Network (9/94)

=====

Article Created: 2 March 1990  
Article Last Reviewed: 31 August 1992

TOPIC -----

I am taking A/UX into an environment that consists of many Sun workstations and IBM systems with AIX. I want to evaluate A/UX with regard to the following:

- Connecting to NFS
- TCP/IP
- X Window System

What is required to make the A/UX ready to connect to the NFS network, and what do I have to do to make the A/UX ready to connect to TCP/IP?

DISCUSSION -----

To connect A/UX 2.0 and 3.0 to a network with TCP/IP and NFS:

- 1) Prepare Ethernet hardware (EtherTalk Card, Coax Ethernet cable, and terminators) and Internet information (Host name, Domain name, IP address, Broadcast address, and netmask), which will be asked for later.
- 2) Bring A/UX 2.0 or 3.0 up in single-user mode.
- 3) Create an NFS kernel with both client and server capabilities. To do this type the command:

```
# /etc/newconfig nfs
```

The "/etc/newconfig nfs" command automatically adds the appropriate modules to the kernel for using NFS.

While newconfig is running, the Internet information mentioned in step 1

will be asked for.

4) Restart A/UX, by selecting Restart from the Special menu:

5) If A/UX is to be a NFS server, the exported file system(s) must be listed in the /etc/exports file. For instance, the entire root file system exported to a host named "sun1", the file should contain:

```
/          sun1
```

6) Update the /etc/hosts file to include all hosts that A/UX communicates with, and update the /etc/hosts.equiv file to include your trusted hosts. Also, let other hosts, like Sun or AIX, know about your A/UX hostname and IP address.

7) Modify the /etc/fstab file to mount your local and remote NFS file systems.

8) Bring A/UX to multi-user mode. To do this, boot to single user mode and then type the command:

```
# init 2
```

9) All TCP/IP and NFS network services, like "rlogin", "ftp", "rcp", "telnet", "showmount", "netstat", "nfsstat", "mount", "ping" and so on, are now ready to perform. "ping" is a nice tool to use to see if your A/UX and/or other hosts are talking to each other.

This process is described in more detail in the "A/UX Network System Administration" manual.

## Aristotle Setup: AppleTalk Slot Assignments (4/97)

Revised: 4/2/97  
Security: Everyone

Aristotle Setup: AppleTalk Slot Assignments (4/97)

=====

Article Created: 27 March 1990  
Article Reviewed/Updated: 02 April 1997

TOPIC -----

The Aristotle Display progrma may generate the error message "AppleTalk must be installed to run this program" when launched. This article describes a possible solution to this problem.

DISCUSSION -----

This error message can occur when the slot assignments are not correctly set. In particular, slot 7 needs to be set to "AppleTalk" when running the Aristotle Display program.

For network startup and general network operations to work correctly, the slot assignments must set as:

Slot 1 (or Slot 2) = AppleTalk  
Slot 7 = AppleTalk  
Startup = AppleTalk

Note: Network startup can take place, most applications can be launched, programming can take place in Applesoft BASIC and files can be saved on any available volumes, even though slot 7 is set to "Your Card".

## Apple IIGS: Displaying in Monochrome Mode

Revised: 6/24/90  
Security: Everyone

Apple IIGS: Displaying in Monochrome Mode

=====

This article last reviewed: 6 March 1990

TOPIC -----

Some of my group's Apple II software applications run in color on the Apple IIGS and look terrible. (Most of the programs with the problem are written in BASIC.) Is there a routine or call for putting the Apple IIGS into monochrome mode?

DISCUSSION -----

What monitor are you using? The AppleColor Composite Monitor (A2M6020) or the AppleColor RGB Monitor (A2M6014)?

AppleColor Composite Monitor

-----

There is a switch behind the front access door that turns the Composite Monitor to a green character on black background display. This will help the displayed image to appear more clearly.

Additionally, the Apple IIGS Control Panel has the Monitor CDEV for selecting color or monochrome monitor. This may help if you're using the Composite Monitor in the single-color mode. This setting affects only the composite output of the Apple IIGS. This is the only method we know for setting the Apple IIGS to monochrome mode.

AppleColor RGB Monitor

-----

There are certain issues that affect the display on the RGB Monitor's graphics page. If the graphic images are not placed on even nibble boundaries, there will be color bleed that many consider unacceptable. On the RGB Monitor, the only solution is to rewrite the programs, with the even nibble boundary issue in mind.

## 3COM EtherLink/NB Card: EtherTalk Incompatibility Problem

Revised: 4/18/91  
Security: Everyone

3COM EtherLink/NB Card: EtherTalk Incompatibility Problem

=====

This article last reviewed: 6 March 1990

TOPIC -----

My office is having trouble with system bombs while using EtherTalk. Can you help?

### Problem Description

-----

Macintosh IIX and Macintosh IICx systems equipped with the 3COM EtherLink/NB card (ASSY 4042- 031 REV A or B) running EtherTalk 1.2 intermittently experience system bombs. Not all Macintoshes display the problem. For instance, given two identical workstations on the same Ethernet segment, only one may experience the problem.

Usually, the system bomb appears in the form of a blank rectangular box in the middle of the screen with no error code or message. However, a couple of users have noticed the System Error 12 appear then disappear. (System Error 12 means that an unimplemented trap was executed.)

We have been working with 3COM for the last two months on this and have determined that our LAN configuration is sound and that all our hardware and firmware is up to specifications. The problem seems to point to the EtherTalk driver, which was written by Apple.

### Correlations

-----

The problem seems to be correlated to the amount of Ethernet traffic on our LAN. During an experiment, I placed an Ethernet bridge between an entire floor that was experiencing the problem, effectively reducing traffic and eliminating the system bombs. Also, during extremely high traffic periods, we noticed that the Macintoshes were experiencing the bombs more frequently.

A Macintosh connected to our network via AppleTalk to a Kinetics FastPath does not experience the system bombs. However, as soon as I connect it to the

Ethernet and activate the EtherTalk driver in the Control Panel, the Macintosh begins to experience the system bombs.

DISCUSSION -----

This is a known problem that tends to surface on networks with high traffic levels. It is due to an incompatibility between the revision A and revision B 3COM EtherLink/NB cards and EtherTalk 1.2 or newer. Just as Apple has released revisions to the EtherTalk NB Card, 3COM has released revisions to their EtherLink/NB cards. The most current is revision L, which works with EtherTalk drivers through version 2.0.1. Contact 3COM for details on their EtherLink/NB card upgrade program.

Something else to note is that the latest version of 3+Share is 1.5. 3COM technical support stated that version 1.3.1 shouldn't be causing any problems in your installation, but that there are enhancements in version 1.5 worth looking into.

For more details, search the Technical Info library under "3COM."

## DAL: dialup and dialvax Problem

Revised: 7/27/93  
Security: Everyone

DAL: "dialup" and "dialvax" Problem

Article Created: 27 March 1990  
Article Reviewed/Updated: 23 July 1993

TOPIC -----

Could you confirm that the following "hosts.cl1" file contains the correct dial-in information to conduct Data Access Language (DAL, formerly known as "CL/1") demos. In question is the "dialup" and "dialvax" routines. All I receive when running these options is a carrier detect and then the line is dropped. Everything has been verified on my side. Do either of these options support line speeds greater than 1200 baud?

Here is the file content:

```
rem::          BE AWARE THAT THIS IS AN EXAMPLE FILE ONLY!!
rem::          You should get your systems administrator to modify it according
rem::          to your site's configuration
rem::          Hosts.cl1 connection names are CASE-SENSITIVE

rem::  This is the DAL config file  hosts.cl1, version 1.0

rem::  Refer to the "Guide to DAL Developer's Toolkit" for documentation.

rem::  This is an example of how to handle the standard (default) login
sequence.
rem::  Use it as a model to build your own custom async login sequence.
rem::  It should work for both VAX/VMS & A/UX.
std:login:3tries:\sexit\r\slo\r:600:2000:\r\^y\^d\w3:\r:\M
\w2\u\r\P\Msword\p\r\P\m$

rem::  a direct 9600 serial line with no login script
direct:async:com1:9600:Noparity:8databits:2stopbits:Bothxonxoff:128:Nodem
direct1200:async:com1:1200:Noparity:8databits:2stopbits:Bothxonxoff:128:Nodem

rem::  same as above (with no login script)
async:async:com1:9600:Noparity:8databits:2stopbits:Bothxonxoff:128:Nodem
```

## ..TIL05267-DAL-dialup\_and\_dialvax\_Problem.pdf

```
rem::  same as above except it uses the com2 serial port
com2:async:com2:9600:Noparity:8databits:2stopbits:Bothxonxoff:128:Nomodem

rem::  1200 baud modem dial up  (with no login script)
dialup:async:com1:1200:Noparity:8databits:2stopbits:Boxonxoff:128:Modem:Tone:9,
,14082539402:32secs:1attempt
dialvax:async:com1:1200:Noparity:8databits:2stopbits:Boxonxoff:128:Modem:Tone:9
,,14082576888:32secs:1attempt

rem::  appletalk (ADSP) connections
rem::  format =>    <<Host Name>>:atalk:<<Decnet Node>>.<<Appletalk Zone>>
nivax:atalk:NIVAX.Network Innovations
nidev:atalk:NIDEV.Network Innovations
nisup:atalk:SUPPORT.Network Innovations

rem:: This is a custom vms async login sequence.
vax:async:com1:9600:Noparity:8databits:2stopbits:Boxonxoff:128:Nomodem
vax:login:3tries:lo:600:2000:\r\^y\w2:\r\Msename\u\r\P\Massword\r\r\P\m$

rem:: This is a custom unix async login sequence.
unix:async:com1:9600:Noparity:8databits:2stopbits:Boxonxoff:128:Nomodem
unix:login:3tries:exit:600:2000:\r\^d\w3:\r\saaa\r:\sbbb\r\Mogin\w2\u\r\P\Massw
ord\r\r\P\m$

rem:: End of Hosts.cl1 (Note: Last line must have a return at the end of the
line.)
```

### DISCUSSION -----

Regarding the two dial-up format examples below:

```
rem::  1200 baud modem dial up  (with no login script)
dialup:async:com1:1200:Noparity:8databits:2stopbits:Boxonxoff:128:Modem:Tone:9,
,14082539402:32secs:1attempt
dialvax:async:com1:1200:Noparity:8databits:2stopbits:Boxonxoff:128:Modem:Tone:9
,,14082576888:32secs:1attempt
```

- 1) These are both good examples of how to program a dial-up connection. To use the dial-up options, you need a valid phone number. You could connect a modem to your local DAL server (VAX or A/UX) and use its phone number, or you could use the services provided by Clear Access Corp. (formerly Fairfield Software Inc.) as describe in the DAL distribution package sent to your office during late December 1989 (see the bottom of page 2 of the "CL/1!" letter included in the mailing).
- 2) All standard RS-232-D speeds are valid with DAL: (Partial list: 75, 110, 300, 600, 1200, 2000, 2400, 3600, 4800, 7200, 9600).

Please note the declaration at the top of the host.cl1 file:

```
rem::          BE AWARE THAT THIS IS AN EXAMPLE FILE ONLY!!
rem::          You should get your systems administrator to modify it according
```

# ..TIL05267-DAL-dialup\_and\_dialvax\_Problem.pdf

```
rem::      to your site's configuration
rem::      Hosts.cll connection names are CASE-SENSITIVE
```

## Apple Software: Where To Get Replacement Disks (3/95)

Revised: 3/16/95  
Security: Everyone

Apple Software: Where To Get Replacement Disks (3/95)

Article Created: 6 March 1990  
Article Reviewed/Updated: 16 March 1995

TOPIC -----

I have Apple software on diskette or CD-ROM. The original floppy or CD-ROM is bad, and I need a replacement. How do I get replacement copies?

DISCUSSION -----

Replacement copies of most Apple software and manuals are available at no charge through the Media Exchange program. You must fill out a media exchange card before returning the defective disks. This card is available from your Authorized Apple Service Provider, or by calling 800-SOS-APPL, who will send you the exchange card.

The disk and exchange card are then sent to:

Apple Computer, Inc.  
Media Exchange Program  
P.O. Box 149112  
Austin, TX 78714-9112

Replacement software is then sent to you once your disk(s) and exchange card are received.

## A/UX 1.0: f77 Compiler Problems and Solution

Revised: 9/15/92  
Security: Everyone

A/UX 1.0: f77 Compiler Problems and Solution

=====

Article Created: 6 March 1990

### Article Change History

-----

08/31/92 - REVIEWED

### TOPIC -----

I am having problems with the f77 compiler for A/UX. Here are some significant faults:

```
C
C new program:
C
      INTEGER*2 I2
      INTEGER*4 I4

      I2=2
      I4=4
      I2=I4
C this line ends in >>>> Termination code 139
      I2=I4-2
C this line ends in >>>> "", line 7: compiler error: can't deal with op NAM

      STOP
      END
C
C new program:
C
      SUBROUTINE test(NAME,NAMLEN)
      INTEGER*2 NAME(1),NAMLEN,
&              I00000

      DATA I00000 /0/
```

```
C this line ends in >>>> Assembler: test.f
C                >>>> AppleLine 9      : invalid instruction name
C                >>>> AppleLine 9      : syntax error
C                >>>> Compiler error in file test.o: assembler error

    NAMLEN=10
    RETURN
    END
```

Due to program volume constraints, there is no practical way to change INTEGER\*2 to INTEGER\*4 as one of the verified f77 problems. Would you recommend a version of this compiler for A/UX? What about the Greenhills Optimizing Fortran compiler or any other known compiler?

#### DISCUSSION -----

We have verified the problem with the above f77 code. It is an A/UX f77 problem; it compiled OK using Greenhills Optimizing Fortran compiler (gf77) under A/UX.

The "Termination code 139" and the subsequent error message have to do with the use of the result INTEGER\*2 variable being assigned by the INTEGER\*4 variable; the conversion between the "int" (4-byte long integer) and the "short" (2-byte long integer) doesn't seem to work.

The "Assembler: ..." and the subsequent error messages were caused by the "DATA" initialization statement; the "f77" seems to expect that the integer variable specified in the DATA statement to be a 4-byte long integer.

As a solution, we suggest that you use Greenhills Optimizing Fortran compiler (available from Unisoft). For more details, search the Technical Info library under "UniSoft."

## Apple II Setup and GS/OS: Compatible Versions

Revised: 6/24/90  
Security: Everyone

Apple II Setup and GS/OS: Compatible Versions

=====

This article last reviewed: 6 March 1990

TOPIC -----

I installed the software from the Apple II Setup 2.1.1 disk (680-5060-B) on top of Apple II Setup 2.0.1. I did the other setup steps and tried to start up an Apple IIGS from the server. A GS/OS-specific file could not be found, and I got an error \$0046.

I went back to Apple II Setup 2.0.1, and all was well.

Can you explain?

DISCUSSION -----

The \$0046 error is a "file not found" error. This error normally occurs because part of GS/OS is not on the startup disk--in this case, the server. For the server to have a working GS/OS system to start up the Apple IIGS, the GS/OS Installer needs to be run from an Apple IIGS that is logged on to the server. Then you install the desired GS/OS configuration on the server volume. We believe that this is what is meant by "did the other setup steps".

If we are correct, it is most likely that an older version of the 16-bit operating system is on the server. The 2.1.1 version was a release specifically for version 5.0.2 of GS/OS. If version 2.1.1 was installed while ProDOS 16 (System Disk 3.2 or earlier) is used on the server, there will be a problem with versions being matched correctly. Version 2.0.1 was designed to work with ProDOS 16, the predecessor to GS/OS. The files used on version 2.0.1 are quite different from the files used with 2.1.1.

We suggest that you use version 2.1.1 of the Apple II Setup Installer with a server having GS/OS 5.0.2 installed. Use version 2.0.1 on servers providing the earlier ProDOS 16 system files, which are found on System Disk 3.2 and earlier.

Also note that GS/OS 5.0 provided a version of Apple II Setup labelled "2.1."  
This version should be used only with GS/OS 5.0. However, the best solution is  
to use GS/OS 5.0.2 and Apple II Setup 2.1.1.

## Apple IIGS: ROM Upgrade Information

Revised: 6/24/90  
Security: Everyone

Apple IIGS: ROM Upgrade Information

=====

This article last reviewed: 6 March 1990

TOPIC -----

I have a question about the ROM Upgrades sent to the field for the new Apple IIGS logic board.

The ROM sent to us by Support Engineering looks like two of the ROM chips on the main logic board. There were no instructions on which chip to replace. Should we have received two chips? If not, which chip is the one to be replaced?

DISCUSSION -----

The ROM that was sent goes in the socket labeled UJ9 (FFEF). The new ROM has 28 pins. If your board has a 32-pin socket at UJ9, put pin 1 of the ROM into hole 3 of the socket. With the notched end of the chip towards the front of the Apple IIGS, there should be two holes exposed on each side of the socket. If the socket has only 28 holes, pin 1 goes to hole 1.

## MacLANConnect Gateway: Information

Revised: 6/24/90  
Security: Everyone

MacLANConnect Gateway: Information

=====

This article last reviewed: 6 March 1990

TOPIC -----

Do you know anyone who has used Miramar System's MacLANConnect Gateway against OS/2 LAN Server EE 1.1? What kind of results are they getting?

DISCUSSION -----

MacLANConnect is a useful product for selling into environments, like OS/2 LAN Server EE and Banyan, where there is no AFP support at this time. We also suspect this product will work in the IBM's mid-range family, although we have not seen it work. They just released version 1.1, in January, which now supports AppleTalk Phase II and works with AppleShare PC 2.0.1.

The basic concept is that you can take an IBM AT/XT/386 and use it as a gateway from AFP to NetBIOS. The NetBIOS side is simply whatever software the server offers. In the case of IBM, it would be the DOS requester of the PC/LAN support software.

The network topology we saw was a single Token Ring network with:

- 1 Macintosh IIX, TokenTalk NB Card, System 6.0.3, AppleShare Client
- 1 PS/2 60, IBM 16/4MB Token Ring Card MCA, As MacLANConnect Gateway
- 1 PS/2 80, IBM 16/4MB Token Ring Card MCA, OS/2 EE 1.1, OS/2 LAN Server 1.1 EE
- 1 PS/2 60, IBM 16/4MB Token Ring Card MCA, PC cc:Mail Client

What we did:

- 1) We loaded the MacLANConnect Gateway with the IBM LAN support 1.11 software.

- 2) We loaded AppleShare PC 2.0.1 on to the MacLANConnect Gateway as instructed in AppleShare documentation.
- 3) We used the PC/LAN Support's DOS requester software to log on to the OS/2 LAN Server and mounted several network drives; that is, V: Y: N:.
- 4) We loaded MacLANConnect software, configured the software through panels similar to AppleShare PC and started the sever process.
- 5) On the Macintosh side, we selected the Chooser and the MacLANConnect Server appeared. We logged on to the server and mounted all published volumes as Macintosh HFS volumes, similar to Novell's.

We were able to use cc:Mail on the Macintosh, access the post office residing on the OS/2 LAN Server, and exchange mail with the PC on the ring loaded with cc:Mail PC. We discovered when loading the protocol stacks that AppleTalk stacks need to be loaded before NetBIOS.

Also, we found that MacLANConnect runs out of memory rather quickly,. We had to adjust the maximum number of open files to accommodate this. We may need to investigate moving the drivers to a higher memory location through a third-party DOS extender.

For more details, search the Technical Info library under "Miramar Systems."

## Macintosh: Displays Greater Than 72 dpi Not Yet Available

Revised: 6/24/90  
Security: Everyone

Macintosh: Displays Greater Than 72 dpi Not Yet Available

=====

This article last reviewed: 6 March 1990

TOPIC -----

I want to implement scanned documents in conjunction with electronic mail. The scanned documents look good when printed but not as nice when viewed on the screen at 72 dpi. I need video cards and monitors that work at 100 or 150 dpi, but I cannot find anything other than 72 or 75 dpi. I don't want to change scale, just resolution.

Can you help?

DISCUSSION -----

As of February, 1990, we don't know of any display system for the Macintosh that provides a resolution higher than 72 dpi without decreasing the size of the displayed image in direct proportion to the increase in resolution. In other words, the higher the screen resolution, the smaller the displayed image.

## Nine-Inch Color Monitor for Macintosh

Revised: 6/24/90  
Security: Everyone

Nine-Inch Color Monitor for Macintosh

=====

This article last reviewed: 6 March 1990

TOPIC -----

I am using a Macintosh as the front end to a new product that will be used in an automobile. I need a 9-inch color monitor with the Macintosh and have located a unit from DisplayTek that has a vertical scan rate of 60Hz or 70Hz (selectable to one or the other only, not adjustable in a range) and a horizontal scan rate of 31.5KHz.

The horizontal can work +/- 0.5KHz from nominal. Is there a video board that works with these specifications? I have been told that an early version of the SuperMac video card might be able to work. As an alternative, is there another 9-inch monitor that I can suggest to them?

DISCUSSION -----

Princeton Graphics makes a 9-inch multisync monitor on a special-order basis only. This monitor should work properly with the Macintosh II video card. For more details, search the Technical Info library under "Princeton Graphic."

## Distributing Apple Fonts Requires License (4/97)

Revised: 4/2/97  
Security: Everyone

Distributing Apple Fonts Requires License (4/97)

=====

Article Created: 6 March 1990  
Article Reviewed/Updated: 02 April 1997

TOPIC -----

What is the policy for distribution of the fonts found in the System Software?  
I want to distribute a HyperCard Stack, and he need to install the New York  
font in it. I also would like to use other fonts, but need to know if it's  
okay to distribute them like this.

DISCUSSION -----

If you are going to distribute a HyperCard stack containing any of the  
following fonts, you will need to get a license from Apple Software Licensing  
to distribute Apple System Software:

|               |           |          |
|---------------|-----------|----------|
| Athens        | Cairo     | Courier  |
| Geneva        | Helvetica | London   |
| Los Angeles   | Mobile    | New York |
| San Francisco | Symbol    | Times    |
|               | Venice    |          |

For information on using the fonts distributed with the LaserWriter family of  
printers or other information licensing Apple products, contact Apple Software  
Licensing at 408-974-4667 or eMail them at [SW.LICENSE@apple.com](mailto:SW.LICENSE@apple.com)

## Font Manager and Printer Driver: How They Relate

Revised: 9/10/92  
Security: Everyone

Font Manager and Printer Driver: How They Relate

=====

Article Created: 6 March 1990

### Article Change History

-----

08/20/92 - REVIEWED  
• For technical accuracy.

### TOPIC -----

Could you give me a brief description of the relationship between the FOND resource, the Font Manager, and the printer driver?

### DISCUSSION -----

The FOND's style mapping and name tables contain the information for matching a PostScript font to a bitmapped font. The style mapping table is used by the LaserWriter driver and contains the font class and character encoding information plus a mechanism for getting the name of the PostScript printer font. When you request to print a particular font and style, the driver checks the "FOND" for a style mapping table. If the table is present, it then looks up the PostScript name of the style to print.

The name table is actually a table within the style mapping table that contains an array of indices that help build the font name suffix for each possible style in the font family. The name table has the following format:

```
NameTable = record
    stringCount : integer;
    baseFontName : str255;
    {strings : array [ 2..stringcount ] of String; }
end;
```

The name table contains the number of strings followed by the base font name (the string count includes the base font name). The base font name is followed by strings containing suffixes or numbers specifying what suffixes to put together to get the real PostScript font name. Here's an example:

```
|_____Helvetica-BoldOblique
```

The "|\_\_\_\_\_" prefix is added by the driver (a vertical slash with six underline characters). The base font name is "Helvetica". The suffix to get the right font name to get the bold and italic style is "-BoldOblique", and the index in the index array for style \$03 (BoldItalic) contains four. For our example, the string list for this font would have the following entries:

```
1 Helvetica
2 9 10
3 9 11
4 9 10 11
5 9 12
6 9 12 9 10
7 9 12 9 11
8 9 12 9 10 11
9 -
10 Bold
11 Oblique
12 Narrow
```

If you take a look at string 4, it has 9, 10, and 11 as entries. If you put these suffixes together you get "-BoldOblique". When the driver gets a name, it checks to see if the printer already contains it. If it does not, the driver checks the System file for a file with the name "HelveBolObl". If it finds one, it dumps the contents of the file to the printer and uses the font. Otherwise, it dumps a QuickDraw bitmap, which gets scaled to the right size.

The printer font filename (in our example HelveBolObl) is derived from the PostScript name using a simple algorithm. The filename is found by dissecting the PostScript name, contained the name table, into pieces based on capital letters and hyphens. The first five letters of the first piece followed by the first three letters of any subsequent components. The maximum number of letters that can compose a filename is 31 characters. This is a restriction of HFS. For example, given the following PostScript names, here are the equivalent printer font file names:

```
Palatino-Italic = PalatIta
Courier-Bold = CouriBol
Times-Roman = TimesRom
```

## PrintMonitor Error -36: Corrupted Volume or WDEF Virus (11/94)

Revised: 11/14/94  
Security: Everyone

PrintMonitor Error -36: Corrupted Volume or WDEF Virus (11/94)

=====

Article Created: 6 March 1990  
Article Reviewed/Updated: 14 November 1994

TOPIC -----

I am getting an interesting error:

Print Monitor found an internal problem:

where = 80  
why = -36

The system configuration is:

Macintosh IICx  
System Software 6.0.3  
Background Printing: On

The problem occurs with different applications.

DISCUSSION -----

This error indicates that Print Monitor encountered an I/O error while trying to open/create the "Spool Folder" or creating the "Spool File". This usually means that the disk that Print Monitor is trying to write to is somehow corrupted. The solution is to back up the disk and reformat it. It is also possible that a virus, such as WDEF, is causing the problem.

## SANE: Accuracy and Performance Information

Revised: 6/24/90  
Security: Everyone

SANE: Accuracy and Performance Information

=====

This article last reviewed: 6 March 1990

TOPIC -----

I am interested in the accuracy of SANE when working with numbers that take SANE to its maximum accuracy potential. Also, what is the performance difference when using the most accurate SANE number format compared to using less accurate formats?

DISCUSSION -----

Though different in detail, the MC68881 and SANE packages are both implementations of the IEEE Standard 754. Following are the range and precision of the data types supported by SANE:

|                           | Single   | Double    | Comp    | Extended   |
|---------------------------|----------|-----------|---------|------------|
|                           | -----    | -----     | ----    | -----      |
| Size (bytes:bits)         | 4:32     | 8:64      | 8:64    | 10:80      |
| Range of binary exponents |          |           |         |            |
| Minimum                   | -126     | -1022     | -       | -16383     |
| Maximum                   | 127      | 1023      | -       | 16383      |
| Significand precision     |          |           |         |            |
| Bits                      | 24       | 53        | 63      | 64         |
| Decimal digits            | 7-8      | 15-16     | 18-19   | 19-20      |
| Decimal range approximate |          |           |         |            |
| Maximum positive          | 3.4E+38  | 1.7E+308  | 9.2E18  | 1.1E+4932  |
| Minimum positive norm     | 1.2E-38  | 2.3E+308  |         | 1.7E-4932  |
| Minimum positive denorm   | 1.5E-45  | 5.0E-324  |         | 1.9E-4951  |
| Maximum negative denorm   | -1.5E-45 | -5.0E-324 |         | -1.9E-4951 |
| Maximum negative norm     | -1.2E-38 | -2.3E-308 |         | -1.7E-4932 |
| Minimum negative          | -3.4E+38 | -1.7E+308 | -9.2E18 | -1.1E+4932 |

If the compiler is making direct calls to the MC68881, accuracy may suffer in some situations. For elemental functions, both SANE and the MC68881 have errors in the least-significant bits of the fraction part of extended-format results, but SANE's errors rarely exceed the last bit, whereas the MC68881 errors may extend to as many as the last five bits. The MC68881 is much more likely to return an error in a double-precision result than SANE is.

Due to the architecture of the Macintosh, and how SANE is implemented on the Macintosh, the extended-precision number format not only provides the most accuracy, but also provides better performance than the computational or double-number formats. The Macintosh converts double and computational numbers into extended number before using them, and thus takes more time than just using the extended-number format.

Single precision provides the most speed, but is hardly ever used because most high-level language compilers today generate code using the extended number format. You can use the single number format, but the code probably would have to be written in assembly language.

For more complete and detailed information, we suggest the "Apple Numerics Manual, Second Edition" from Addison-Wesley.

## Macintosh Portable: Printing to a LaserWriter IISC

Revised: 7/29/92  
Security: Everyone

Macintosh Portable: Printing to a LaserWriter IISC

=====

Article Created: 7 March 1990  
Article Last Reviewed: 28 July 1992  
Article Last Updated: 29 July 1992

TOPIC -----

I have a Macintosh Portable with 2MB RAM, and no INITs. I connected a LaserWriter IISC and am printing an Excel 2.2 spreadsheet. The spreadsheet is approximately 12 or 14 columns and about one page. I use landscape mode, reduce it to 75%, and print gridlines. This process takes five minutes to print. Is this print time typical, or is there something wrong?

DISCUSSION -----

This is an issue that is inherent to applications such as Excel, Microsoft Word, MacDraw II, and other programs that don't display a watch or animated cursor while processing a print job.

The problem is that applications like Excel do not put up an animated or watch cursor while processing a print job. Since no other activity is taking place (like typing, moving the mouse, and so on), the Macintosh Portable falls into "Rest" mode. This is where 64 wait states are inserted so that the effective processor speed is slowed to 1MHz (this is done to reduce power consumption when no activity is taking place). If application manufacturers follow HIG and put up an animated or watch cursor, the CPU does not Idle and will finish the print job slightly faster than an Macintosh SE.

A suggested workaround is to deactivate "Rest", one of the power-saving features of the Macintosh Portable. This is done by opening the Portable CDEV and "Option-Clicking" on the words "Minutes until Automatic Sleep". A dialog box appears describing "Rest" and gives you the opportunity to turn "Rest" off. You can also prevent idle (aka "Rest") by performing actions such as moving the mouse, typing on the keyboard, and so on.

Using a document similar to the one described above, these were our findings:

Macintosh Portable

-----

5 minutes 8 seconds with idle ON

2 minutes 55 seconds with idle OFF

Macintosh SE

-----

3 minutes 8 seconds

In summary, this is an Excel compatibility problem that occurs on the Macintosh Portable when printing to any printer, not just the LaserWriter IISC. In addition, a user should have the 4X fonts installed for maximum performance when printing text in portrait. The fonts are bitmapped and can be printed directly from the Macintosh screen to the LaserWriter IISC. Printing is a little faster, too, when they are present. When printing horizontally or from graphics packages that use regions instead of polygons or bitmaps, performance suffers.

## A/UX: Sources for BSD Extensions (8/94)

Revised: 8/23/94  
Security: Everyone

A/UX: Sources for BSD Extensions (8/94)

Article Created: 7 March 1990  
Article Reviewed/Updated: 19 August 1994

TOPIC -----

Can you give me a source for BSD 4.3 extensions offered with A/UX, like signals and streams, or point me to a list of these items?

DISCUSSION -----

Currently, there is no document that lists and describes all 4.[23] extensions offered by A/UX. Lists are scattered and explained among various A/UX documents. It is difficult to list them individually. However, this should provide some of the Berkeley BSD 4.[23] features supported by A/UX:

- TCP/IP Berkeley-Style network support. It is called B-Net in A/UX. The supported protocols include:

- IP (Internet Protocol, RFC791)
- UDP (User Datagram Protocol, RFC768)
- TCP (Transmission Control Protocol, RFC793)
- ICMP (Internet Control Message Protocol, RFC792)
- ARP (Address Resolution Protocol, RFC826)
- Telnet (RFC854)
- SUBNET (RFC950)
- FTP (File Transfer Protocol, RFC959)
- SMTP (Simple Mail Transfer Protocol, RFC821)
- BIND (Berkeley Internet Name Domain)

All servers and service programs are in the /etc/servers and /etc/services files. The programming interface routines are in A/UX Programming Reference manual, sections 2N and 3N, like accept(2N), bind(2N), connect(2N), getsocketname(2N), getsocketopt(2N), listen(2N), recv(2N), select(2N), send(2N), socket(2N), and so on.

- Berkeley-Style 4.[23] signals and system calls, like sigblock(2),

sigpause(2), sigsetmask(2), sigstack(2), sigvec(2), killpg(2), and so on.

- Berkeley 4.[23] utility programs are in the /usr/ucb directory.
- C shell
- Berkeley-Style dump.BSD, rdump, restore, rrestore utilities.
- Termcap database and text editors, like vi and ex.
- Other utilities, like symbolic link, symbolic debugger, printenv, and so on.

Note that STREAMS is not Berkeley; it belongs to System V.3.

## ProFile: Disk Full Possible Causes and Fixes

Revised: 6/29/90  
Security: Everyone

ProFile: "Disk Full" Possible Causes and Fixes

=====

This article last reviewed: 7 March 1990

TOPIC -----

An enhanced Apple IIe and ProFile 5MB hard disk is getting consistent Disk Full errors in an Applesoft BASIC program under ProDOS 8 1.8 and BASIC.SYSTEM 1.4. The errors have been increasing in frequency such that they happen two and three times per day. (They happened two or three times per year previously.) The hard disk is only 15% full, and two ProDOS volume checker programs (Mr. Fixit by Glen Bredon, and BagOfTricks2 by Quality Software) report no errors on the volume. The interface card has the new ROM, part number 341-0299.

### System Configuration

-----

AuxSlot: Apple Extended 80-Column Card  
Slot 1: empty  
Slot 2: Apple Super Serial Card  
Slot 3: empty  
Slot 4: empty  
Slot 5: Applied Engineering TimeMaster II H.O. (clock card)  
Slot 6: Apple DuoDisk Controller  
Slot 7: Apple ProFile Interface

The program lines that generate the error are always PRINT statements that are printing data to an open ProDOS sequential text file. There is nothing unusual about the method used; that is, OPEN, WRITE, PRINT, CLOSE.

Can you pinpoint the probable cause of this problem? Could it be a problem in BASIC.SYSTEM 1.4, or a ProFile or controller hardware problem, or something in the 341-0299 ROM?

DISCUSSION -----

We doubt that there is a problem with the hardware. It seems to be related to the way things are handled on the ProFile disk under ProDOS 8. Here are some

possible causes:

- Even though the error message deals with disk space, it actually may be that the directory is full; that is, there is no space for additional file entries in the disk directory. This would be especially true in a system that stores many small files.
- ProFiles "spare out" any bad blocks found by its startup procedure. If all of the available blocks have been spared out and another block needs a spare, an error stating that the disk is full might be reported. In this instance, all spare blocks have been used and no more are available, creating a form of disk full. The ProFile has only 32 spare blocks for use. Once used, the ProFile does not allocate any additional spare blocks.
- With many small files being written and rewritten to the ProFile, fragmentation can occur more quickly than if a few large files are used. With a heavily-fragmented disk, a "Disk Full" message might occur.

Some possible solutions have been suggested:

- If you have the Pascal "Crunch" utility, run this utility against the ProFile to resolve possible fragmentation of the drive.
- Use more subdirectories inside subdirectories to help slow the filling of directory entries.
- Do a file-by-file backup of the ProFile. Then reformat and restore the files to the ProFile.

## GS/OS 5.0.2: File Not Found Error

Revised: 6/29/90  
Security: Everyone

GS/OS 5.0.2: "File Not Found" Error

=====

This article last reviewed: 7 March 1990

TOPIC -----

I work at an Apple IIGS (1MB RAM) that is on a network with Macintosh SE/30 with 4MB RAM and HD80 SC File Server.

After updating the GS/OS system files on the server via the Apple IIGS Installer, updating Aristotle likewise, and reinstalling the Apple II Setup disk, I received the following error message:

Sorry, system error \$0046 occurred while loading the start FST file.

I checked all access privileges, and they are not a problem. Can you help?

DISCUSSION -----

The \$0046 error is a "file not found" error. There are two ways this can happen when starting up from the network.

- 1) The Icons folder and the System folder need privileges set to the Bulletin Board item found in the GS/OS Icon Info menu item. If these folders are set otherwise, GS/OS cannot "find" the files inside these two folders.
- 2) There is a file missing or misplaced on the server volume that the Apple IIGS requires for startup. Usually reinstalling GS/OS onto the server resolves the problem.

## ProDos GS/OS, and Instant Pascal: Launching and Quitting

Revised: 3/27/90  
Security: Everyone

ProDos GS/OS, and Instant Pascal: Launching and Quitting

=====

This article last reviewed: 7 March 1990

TOPIC -----

We have an AppleTalk network system and have discovered some strange behavior with certain applications on the Apple II.

Using current software, there are three shell programs (besides BASIC) available for AppleTalk network system users. They are Aristotle, the Finder, and Let's Share. We have found that some applications work perfectly when launched from one of the shells, but not when launched from another. Also, when quitting, some return to the shell from which they were launched, while others return directly to the File Server Log-On screen.

Here are some examples:

- Mavis Beacon Teaches Typing (Software Toolworks) works fine when launched from Aristotle or the Finder, but not from Let's Share.
- Medley (Milliken) always returns the user to the Log-On screen on quitting.

Some applications seem to return the user to the shell from which they were launched, while others return the user to the server-defined startup application. (I have no concrete examples of this, but here's an illustration)

- The user logs on and goes to Aristotle, his startup application. He launches the Finder from Aristotle and from there launches "Application X". On quitting Application X, he is returned to the Finder, and on quitting the Finder (Special Menu, Shut Down, Return to Launching Application), he is returned to Aristotle.
- The user repeats the above process to get to the Finder, but this time launches "Application Y". On quitting Application Y, he is returned directly to Aristotle, even though he launched Application Y from the Finder.

Do you have any clues about these differences? Do some of these shells leave memory in a different state than others when they launch applications? Are there any standards for this sort of thing? Is Let's Share a known offender, or does it follow whatever rules there are? Is there a standard GS/OS or ProDOS 16 Quit call? Is everyone not implementing it correctly?

Here's a related question:

I have tried putting ProDOS applications that reside on floppy disks into Aristotle menus. If I put the disk in the drive and choose the menu item, the application launches properly and, on quitting, seems to return the user to Aristotle without a hitch. However, a colleague reports that when doing this with Instant Pascal, the server connection is dropped somewhere, so quitting fails. Do some applications disable network listeners or trash the memory where network files resides? Is there any way to tell what might work in this fashion and what might not?

#### DISCUSSION -----

The behavior is determined by which operating system the application is written under: GS/OS or ProDOS 8.

The ProDOS 8 quit command is quite simple and does not have the ability to put the name of the application to return to on the return stack. ProDOS applications "quit to" the program named Start in the GS/OS volume. As shipped, this is the Finder. However, if the startup program has been set in the AppleShare Admin application, the Finder may not be the "start" program any longer. Whatever is set in Admin is the application to which the ProDOS 8 programs return.

GS/OS applications have the ability to put the name of the program to which one returns onto the return stack. If properly written, quitting a GS/OS application returns the user to the same application that launched the GS/OS program just quit.

For your examples:

- We defer to Russ Systems about all Let's Share issues.
- We are still trying to work a variety of issues out with Medley. We will add this one to the list to investigate.
- With Aristotle (ProDOS 8) as the Admin set startup application, launching the Finder (GS/OS), then launching "Application X" (apparently, a GS/OS application from the behavior described), and quitting "Application X", it would be correct to finish at the Finder, if "Application X" is, indeed, a GS/OS application. Quitting the Finder (GS/OS) would then return to the application that launched it, Aristotle.
- In the next example, instead of launching "Application X", the user launches "Application Y" (apparently, a ProDOS 8 application from the behavior described), then quits "Application Y", and finishes in Aristotle. This would be the correct behavior for a ProDOS 8 "Application Y".

Instant Pascal has several issues associated with it. The primary issue is that it is neither a ProDOS nor a GS/OS application. Instant Pascal has its own operating system with its own input/output routines. These I/O routines know nothing about the network. It is, thus, totally logical that Instant Pascal disregards all network activities. The only solution is to rewrite the Instant Pascal operating system. It is unlikely that this solution will ever be considered.

## EtherTalk NB Revision K card: Problem with Macintosh IICI

Revised: 1/6/93  
Security: Everyone

EtherTalk NB Revision K card: Problem with Macintosh IICI

=====

Article Created: 21 March, 1990

### Article Change History

-----

01/05/93 - REVIEWED  
•For technical accuracy

### TOPIC -----

Apple engineering has discovered a performance problem using an EtherTalk NB Revision K card and EtherTalk 2.0.1 or 2.0.2 software on a Macintosh IICI that is using on-board video and 4 or more colors (in 2-bit or greater mode). Ethernet performance is degraded in this situation.

### DISCUSSION -----

To avoid Ethernet performance degradation on a Macintosh IICI, try any of these three alternatives:

- Use an EtherTalk NB Revision L card, or
- Do not use on-board video (i.e. use a video card), or
- Use only black and white video (1-bit video)

If you're using EtherTalk software, the Ethernet performance can be improved somewhat by starting the Macintosh IICI in 1-bit video and later switching to 2-bit or more video. We have found this workaround to be effective when using EtherTalk software (AppleTalk), but not MacTCP software (for example, MacX.)
